**Faculty : Science**

Zinc oxide nanoparticles (ZnO NPs) are widely applied in various industrial products such as cosmetics, pharmaceutical, and rubber production. However, this nanoparticle is classified as extremely toxic for the aquatic environment, particularly fish. Moreover, to date, there have been no systematic studies of the toxicity of ZnO NPs to the same species of organism in saltwater *versus* freshwater conditions, or during graded salinity changes. The objectives of this study are 1) to determine the median lethal concentration (LC<sub>50</sub>) of ZnO NPs for the embryos of Javanese medaka (*Oryzias javanicus*) in different types of water (ultra-pure, deionized and dechlorinated tap water), 2) to evaluate developmental toxicity of ZnO NPs by chronic exposure on the embryo of Javanese medaka, and 3) to assess the interactive effects of salinity and ZnO NPs by chronic exposure on the embryo of Javanese medaka. The experiments were conducted in a completely randomized design with three replicates for each concentration. The acute toxicity tests were conducted to determine the 96 h median concentration (LC<sub>50</sub>) of ZnO NPs for Javanese medaka embryos in different types of water. Results demonstrated the 96 h LC<sub>50</sub> of ZnO NPs for Javanese medaka embryos were determined 0.6438 mg/L, 1.333 mg/L, and 2.251 mg/L in ultra-pure, deionize, and dechlorinated tap water, respectively. Chronic exposure of ZnO NPs on Javanese medaka's embryos at concentration of 0-25 µg/L was also conducted for 21 days. The heart rate of exposed Javanese medaka embryos increased as the concentration of ZnO NPs increased and showed significantly higher heart rate when it compared with control at 5, 8 and 11 dpe. In general, the mortality of embryos increased and the hatching rates were decreased as the concentration of ZnO NPs were increased. Also, series of abnormalities such as low pigmentation, fin rot, spinal deformities, cranial oedema, yolk sac oedema, precordial oedema, and cranial facial were observed in treatment groups. Javanese medaka embryos were also exposed to 25, 50, and 100 µg/L of ZnO NPs in two different salinity levels (5 and 18 ppt) in this study. The results showed that the toxicity of ZnO NPs on Javanese medaka embryos decreased as salinity of

suspension increased. For instance, in contrast to control, exposed embryos to ZnO NPs at 5 ppt showed significantly higher heart rates to 25, 50 and 100  $\mu\text{g/L}$  of ZnO NPS at 5, 8, and 11 dpe. However, at 18 ppt significantly lower heart rate to 25, 50 and 100  $\mu\text{g/L}$  of ZnO NPs were only observed at 5 dpe. In addition, mortality of exposed Javanese medaka embryos were increased by increasing concentration of ZnO NPs at both salinity level but in contrast to control, significantly higher mortality were observed at 5 ppt at the end of the experiment. Moreover, hatching of exposed embryos decreased as the concentration of ZnO NPs increased at both salinity level. Although, only significantly lower hatching rate were observed at 5 ppt when it compared to control. Furthermore, abnormalities such as low pigmentation, oedema, and tail malformation were observed in treatment groups at both salinity levels throughout the experiment, but abnormalities were more obvious at 5 ppt compared to 18 ppt. This study has revealed that ZnO NPs were extremely toxic to the embryo of Javanese medaka in different types of water, and there was a strong correlation between toxicity of ZnO NPs and salinity of suspension. The finding of this study can strengthen the creation of Javanese medaka as a model organism for tropical areas in aquatic nanoecotoxicological studies. Furthermore, the LC50 value is a valuable criterion for nanoecotoxicity; it is not a representative concentration of contaminants in aquatic environments, but it is essential for indicating the toxicity of certain pollutants. Although the concentrations of ZnO NPs in Malaysia aquatic ecosystem is not yet reported, the result of this showed that this hazardous chemical has the potential to have significant impacts on aquatic ecosystems and its living organisms even at environmental relevant concentration.

sebagai memenuhi keperluan untuk ijazah Master Sains

**EMBRIOTOKISITI NANOPARTIKEL ZINK OKSIDA TERHADAP MEDAKA  
JAWA (*Oryzias javanicus* BLEEKER, 1854)**

Oleh

**AMIN NAWEEDULLAH**

Nanopartikel zink oksida (ZnO NP) telah digunakan secara meluas dalam pelbagai produk perindustrian seperti pengeluaran produk kosmetik, farmaseutikal dan getah. Walau bagaimanapun, nanopartikel ini telah diklasifikasikan sebagai sangat toksik pada persekitaran akuatik, terutamanya kepada ikan. Selain itu, sehingga kini, masih belum ada kajian sistematik mengenai ketoksikan ZnO NP terhadap spesies organisma yang sama dalam keadaan air masin berbanding air tawar, atau semasa perubahan perbezaan kemasinan secara berperingkat. Objektif kajian ini adalah 1) untuk menentukan median kepekatan kematian ( $LC_{50}$ ) bagi ZnO NP terhadap embrio Jawa medaka (*Oryzias javanicus*) dalam jenis air berbeza (ultra-tulen, ternyahion dan air paip ternyahklorin), 2) untuk menilai ketoksikan pengembangan ZnO NP melalui pendedahan kronik terhadap embrio Jawa medaka, dan 3) untuk menilai kesan interaktif kemasinan dan ZnO NP melalui pendedahan kronik terhadap Jawa embrio medaka. Eksperimen telah dijalankan dalam reka bentuk rawak dengan tiga ulangan untuk setiap kepekatan. Ujian ketoksikan akut dilakukan untuk menentukan kepekatan median kematian ( $LC_{50}$ ) 96 jam ZnO NP pada embrio Jawa medaka dalam pelbagai jenis air berbeza. Keputusan menunjukkan 96 jam  $LC_{50}$  ZnO NP pada embrio Jawa medaka ditentukan masing-masing pada 0.6438 mg/L, 1.333 mg/L dan 2.251 mg/L dalam air ultratulen, air ternyahion, dan air paip ternyahklorin. Pendedahan kronik ZnO NP pada embrio Jawa medaka pada kepekatan 0-25  $\mu\text{g/L}$  juga dijalankan selama 21 hari. Kelajuan jantung embrio ikan medaka Jawa telah meningkat apabila kepekatan ZnO NPs meningkat dan keputusan telah menunjukkan peningkatan kelajuan jantung yang signifikan apabila dibandingkan dengan kawalan pada 5, 8 dan 11 hari selepas pendedahan (dpe). Secara amnya, kematian embrio meningkat dan kadar penetasan menurun apabila kepekatan NP ZnO meningkat. Selain itu, siri keabnormalan seperti pigmentasi rendah, reput sirip, kecacatan tulang belakang, edema tengkorak, edema kantung kuning telur, edema prekordial dan kranial diperhatikan dalam kumpulan rawatan. Embrio Jawa medaka juga didedahkan kepada 25, 50, dan 100  $\mu\text{g/L}$  NP ZnO dalam dua tahap kemasinan yang berbeza (5 dan 18 ppt) dalam kajian ini. Keputusan menunjukkan ketoksikan ZnO NPs pada embrio Jawa medaka menurun

apabila kemasinan meningkat. Sebagai contoh, berbanding dengan kawalan, embrio yang terdedah kepada ZnO NPs pada 5 ppt menunjukkan kadar denyutan jantung yang jauh lebih tinggi kepada 25, 50 dan 100  $\mu\text{g/L}$  ZnO NPS pada 5, 8, dan 11 hari selepas pendedahan. Walau bagaimanapun, pada 18 ppt, kadar denyutan jantung yang lebih rendah dengan ketara kepada 25, 50 dan 100  $\mu\text{g/L}$  NP ZnO hanya diperhatikan pada 5 hari selepas pendedahan. Di samping itu, kematian embrio Jawa medaka yang terdedah telah meningkat dengan meningkatkan kepekatan ZnO NP pada kedua-dua tahap kemasinan tetapi berbeza dengan kawalan, kadar kematian yang jauh lebih tinggi diperhatikan pada 5 ppt pada akhir eksperimen. Selain itu, penetasan embrio terdedah menurun apabila kepekatan ZnO NP meningkat pada kedua-dua tahap kemasinan. Namun, hanya kadar penetasan yang jauh lebih rendah diperhatikan pada 5 ppt apabila dibandingkan dengan kawalan. Tambahan pula, keabnormalan seperti pigmentasi rendah, edema dan kecacatan ekor diperhatikan dalam kumpulan rawatan pada kedua-dua tahap kemasinan sepanjang eksperimen, tetapi keabnormalan lebih jelas pada 5 ppt berbanding 18 ppt. Kajian ini telah mendedahkan bahawa ZnO NP adalah sangat toksik kepada embrio Jawa medaka dalam pelbagai jenis air, dan terdapat korelasi yang kuat antara ketoksikan ZnO NP dan kemasinan. Dapatan kajian ini dapat membuktikan Jawa medaka sebagai model organisma untuk kawasan tropika dalam kajian nanoekotoksikologi akuatik. Tambahan pula, nilai LC50 adalah kriteria yang bernilai untuk nanoekotoksikologi; ia bukanlah kepekatan wakil pencemar dalam persekitaran akuatik, tetapi ia adalah penting untuk menunjukkan ketoksikan bahan pencemar tertentu. Walaupun kepekatan NP ZnO di ekosistem akuatik Malaysia masih belum dilaporkan secara terperinci, keputusan ini menunjukkan bahawa bahan kimia berbahaya ini mempunyai potensi untuk memberi kesan yang ketara ke atas ekosistem akuatik dan organisma hidupnya walaupun pada kepekatan yang berkaitan dengan persekitarannya.

## ACKNOWLEDGEMENTS

In the name of Allah S.W.T., the Most Gracious and the Most Merciful,

First of all, I would like to thank almighty Allah S.W.T. for giving me the strength, knowledge, ability, and opportunity to undertake this study and to preserve and complete it satisfactorily. This accomplishment would not have been achievable without his blessings.

My deepest appreciation and gratitude to my supervisor, Dr. Syaizwan Zahmir Zulkifli, as well as members of supervisory committee (Prof. Dr. Ahmad Ismail and Assoc. Prof. Dr. Mohammad Noor Amal Azmai) for their invaluable ideas, care, commitment, suggestions, encouragement, and enthusiasm during the whole period of this study program.

My acknowledgment would be incomplete without thanking my senior laboratory-mates (Dr. Musa Adamu Ibrahim, Nur Amiera Kamardin, and Munirah Hanapiah) for the guidance and strong support throughout this study. My unconditional love to my beloved parents Mr. Aminullah Ziai and Mrs. Farida Alam Ziai and my siblings for their everlasting love, care, continuous encouragement, moral support, motivational phrases, and constant prayers, which always cheers me up and drives me to complete this research work successfully. I love you all very much. Finally, for the rest I could not mention, believe me, you are not forgotten.

This thesis was submitted to the Senate of Universiti Putra Malaysia and has been accepted as fulfilment of the requirement for the degree of Master of Science. The members of the Supervisory Committee were as follows:

**Syaizwan Zahmir Zulkifli, PhD**

Senior Lecturer  
Faculty of Science  
Universiti Putra Malaysia  
(Chairman)

**Mohammad Noor Amal Azmai, PhD**

Associate Professor  
Faculty of Science  
Universiti Putra Malaysia  
(Member)

**Ahmad Ismail, PhD**

Professor  
Faculty of Science  
Universiti Putra Malaysia

4.30	Abnormalities of Javanese medaka's embryos exposed to different concentration of ZnO NPs at 5 ppt (A) coagulated at 25 $\mu\text{g/L}$ ZnO NPs, (B) failed hatching at 50 $\mu\text{g/L}$ ZnO NPs, (C) Hatching delay at 100 $\mu\text{g/L}$ ZnO NPs, (D) at 25 $\mu\text{g/L}$ ZnO NPs, (E) at 50 $\mu\text{g/L}$ ZnO NPs and (F) at 100 $\mu\text{g/L}$ ZnO NPs	73
4.31	Abnormalities of Javanese medaka embryos at 2 days post hatched exposed to different concentration of ZnO NPs at 5 ppt (A) and (B) at 25 $\mu\text{g/L}$ ZnO NPs, (C) and (D) at 50 $\mu\text{g/L}$ ZnO NPs, (E) and (F) at 100 $\mu\text{g/L}$ ZnO NPs	74
4.32	Abnormalities of Javanese medaka's embryos exposed to different concentration of ZnO NPs at 18 ppt (A) coagulated at 50 $\mu\text{g/L}$ ZnO NPs, (B) Hatching delay at 100 $\mu\text{g/L}$ ZnO NPs, (C) at 25 $\mu\text{g/L}$ ZnO NPs, and (D) at 50 $\mu\text{g/L}$ ZnO NPs	75
4.33	Abnormalities of Javanese medaka embryos at 2 days post hatched exposed to different concentration of ZnO NPs at 18 ppt (A) 25 $\mu\text{g/L}$ ZnO NPs, (B) 50 $\mu\text{g/L}$ ZnO NPs, (C) and (D) 100 $\mu\text{g/L}$ ZnO NPs	76

## LIST OF ABBREVIATIONS

%	Percent
°C	Degree Celsius
µg	Microgram
mg	Milligram
g	Gram
kg	Kilogram
DO	Dissolved oxygen
NPs	Nanoparticles
BP	Bulk particles
UV	Ultra violet
LC <sub>50</sub>	Median lethal concentration
nm	Nano meter
µm	Micro meter
MeO-NPs	Metal oxide nanoparticles
eV	Electron volt
mV	Mega volt
WWTPs	Waste Water Treatment Plants
L	Liter
DOM	Dissolved organic material
pH	Potential of hydrogen
mg/L	Milligram per liter
µg/L	Microgram per liter
ppt	Parts per thousand
hr	Hour
hpf	Hour post fertilization
dpe	Day post exposure
ROS	Reactive oxygen species

XRD	X ray diffraction
TEM	Transmission electron microscopy
DLS	Dynamite light scattering
OECD	Organization for economic co-operation and development
HBpM	Heart beat per minutes

## CHAPTER 1

### INTRODUCTION

#### 1.1 General introduction

Currently, several dangerous chemicals are considered a global threat to humans, other organisms and also the environment itself. Nevertheless, from time to time, the world is constantly generating and introducing large amounts of chemical substances into the environment. At the same time, the effects on organisms and the environment of these substances are not well known. Among evolving chemicals, nanoparticles (NPs) are one of those which are described as a particle with at least one dimension between 1 and 100 nm with different characteristics from bulk materials (Miao et al., 2010), and nanotechnology is known as the use of these materials (Patibandla et al., 2018). In scientific writing, the word nano, comes from the Greek nanos, which means dwarf, is becoming more prevalent. Nano is also commonly used as an adjective to denote objects, systems, or phenomena that have properties resulting from nano-meter size (one-billionth of a meter or  $10^{-9}$ ) structure (Buzea et al., 2007). Nanotechnology has recently developed as a rapidly growing market with efficient effects on major economic sectors with novel and unique properties that have been used in a diverse group of consumer goods such as agriculture, cosmetics, electronics, textiles, and pharmaceuticals (Kahru et al., 2010; Li et al., 2013; Rajput 2018). Based on the core material, NPs can categorize through inorganic, organic, carbon based and composite based NPs (Rajput et al., 2018). In recent years, the production and distribution of NPs have gradually increased. According to BCC Research (2019), commercial production of NPs is estimated to increase unitary from approximately 223,060 metric tons in 2014 to approximately 584,984 metric tons in 2019, with a compound annual growth rate of 21.1% from 2014 to 2019. Meanwhile, in 2017 the global market for nanoparticles was \$2.0 billion and is expected to raise \$7.3 billion by 2022. One of the important groups of these new materials are metallic NPs (Shaw et al., 2011), and have been widely implemented and monitored for their toxic effects on the activity, abundance, and diversity of living organisms and due to their antimicrobial activity they have been used as biocides to inhibit or limit the growth of microorganisms (Rajput et al., 2018). Besides metallic NPs, metal oxide NPs (MeO-NPs) are also widely used and implemented in commercial and industrial materials. Although bulk metal oxide products also produce massively in a wide range of commercial and industrial products.

Among several NPs, zinc oxide nanoparticles (ZnO NPs) are known as one of the most efficiently used in the nano-scale range with a wide bandgap and large excitonic binding energy (Sabir et al., 2014), high stability, anticorrosion and photo-catalytic properties (Hao et al., 2013), non-migratory, fluorescent, piezoelectric, absorptive, and scatters ultraviolet light (Li et al., 2018), diverse nanostructures (Bai et al., 2010), and antimicrobial activity (Pereira et al., 2019). Zinc oxide NPs are already extensively implemented in consumer goods such as paints, UV filters, biosensors, paper, plastics, ceramics, building materials, rubber, power electronics, coatings, feed, photocatalytic,

degradation of textiles, and printed matter (Brun et al., 2014; Wong et al., 2014). ZnO NPs, which are the third most widely applied metal-based NPs with an approximate world-wide total production of 550 to 33,400 tons (Rajput et al., 2018), can reach the environment, particularly the aquatic environment by (1) wastewater which contains the highest amount of ZnO NPs (0.3–0.4 µg/L), (2) direct use and (3) deposition from the air compartment (Vale et al., 2016; Poynton et al., 2019).

Since ZnO NPs are already introduced directly or indirectly into the environment, particularly the aquatic environment, they may constitute a threat to the aquatic environment (Li et al., 2018). They can be extremely toxic and as an aquatic environmental risk due to their negative impacts on different aquatic living things, including bacteria, algae, crustaceans, ciliates, and fishes (Cong et al., 2017). Meanwhile, studies related to ZnO NPs toxicity on aquatic vertebrate organisms have concentrated largely on fish, in particular zebrafish. Several reports have shown that ZnO NPs can be highly toxic to zebrafish, particularly in the early developmental stages, the key emphasis of those studies has been on acute toxicity studies of aquatic species. At the same time, the chronic toxicity studies of ZnO NPs were surprisingly scarce (Xiong et al., 2011; Zhao et al., 2013). Furthermore, serious threats and higher toxicity compared to other NPs in aquatic environments have been reported in recent studies for ZnO NPs. For instance, Zhu et al. (2008) reported that ZnO NPs showed higher toxicity compared to TiO<sub>2</sub> NPs and Al<sub>2</sub>O<sub>3</sub> NPs on the early life stage of zebrafish. Another study that has shown ZnO NPs are more toxic than TiO<sub>2</sub> NPs is the study of Bhuvaneshwari et al. (2017), who reported 27.62 and 71.63 mg/L for ZnO NPs and 117 and 120.9 mg/L for TiO<sub>2</sub> NPs as 48 h LC<sub>50</sub> on *Artemia salina* under pre-UV-A and visible light conditions.

*Oryzias javanicus* (Javanese medaka) belongs to the Adrianichthyidae family (Magtoon & Termvidchakorn, 2009). This species is widely distributed in Asian countries and highly adaptable to fresh, brackish, and saltwater (Inoue & Takei, 2002). The sensitivity of the species belonging to this family makes it an ideal test organism for toxicology and ecotoxicology studies. Recent studies have indeed used Javanese medaka as the test organism because of their high adaptability to both freshwater and saltwater, broad geographical range and availability throughout the year (Ismail & Yusof, 2011; Yusof et al., 2012; Woo et al., 2012), short life span and life cycle, fast development (Salleh et al., 2017; Yusuff et al., 2018), hardy, easy to identify and cultivate, short spawning period <1 min, and their transparent eggs (Ibrahim et al., 2020). These properties make it a suitable choice for studies, especially studies that involve early life stages.

They are several significant sources of information on ZnO NPs that can induce mortality at high concentration, while surprisingly data for environment relevant concentration that can caused adverse effects of the whole-body system in a long period are not reported yet. The endpoint of this study is to observe the impairment and abnormalities in the embryo and larva of Javanese medaka. The chosen endpoints provide ecological importance, as the low concentration of ZnO NPs has an environment relevant. Meanwhile, the idea that water chemistry can affect the fate and behavior of chemicals, and their subsequent bioavailability to fishes, is well established but, to date, there have been no systematic studies of the toxicity of NPs to the same species of organism in saltwater versus

freshwater, or during graded salinity changes. Moreover, the selected endpoints of ZnO NPs exposure in Javanese medaka have not been studied recently and to date.

## **1.2 Objectives**

The objectives of this study are:

- i. To determine the lethal concentration ( $LC_{50}$ ) value of ZnO NPs by acute exposure on the embryo of Javanese medaka in different types of water (ultra-pure, deionized, and dechlorinated tap water).
- ii. To determine the developmental toxicity of ZnO NPs by chronic exposure on the embryo of Javanese medaka.
- iii. To evaluate the interactive effects of salinity and ZnO NPs by chronic exposure on the embryo of Javanese medaka.
