MULTI DEPOT DYNAMIC VEHICLE ROUTING PROBLEM WITH STOCHASTIC ROAD CAPACITY FOR EMERGENCY MEDICAL SUPPLY DELIVERY IN HUMANITARIAN LOGISTICS

By

WADI KHALID BIN ANUAR

June 2022

Chairman : Lee Lai Soon, PhD
Institute : Mathematical Research

As part of humanitarian logistics research for emergency medical supply delivery during disaster, the modelling and solution of a Multi Depot Dynamic Vehicle Routing Problem with Stochastic Road Capacity (MDDVRPSRC) is presented. Based on the chaotic setting from a disaster event, the model and solution proposed are validated and analysed through a Decision Support System (DSS), MDDVRPSRC DSS. The model proposed is based on Markov Decision Processes (MDP) modelling framework as part of reinforcement learning (RL) solution approach. Through this model, multi objectives, multi depot, multi trip and split delivery among homogeneous fleet of vehicle are addressed. Moreover a stochastic road capacity distribution where its mean deteriorates over time is also depicted in the problem.

To solve the proposed model, an Approximate Dynamic Programming (ADP) approach is applied focusing on the lookahead approach. Specifically a PDS - Rollout Algorithm (PDS-RA) is adopted. Five variants of constructive base heuristics, Teach Based Insertion Heuristic (TBIH-1 - TBIH-5) are proposed complementing the PDS-RA when dealing with the lookahead rollout involving stochastic road capacity.

The computational results obtained are compared with a matheuristic approach. From this novel method, exact CPLEX computation is executed at every rollout decision epoch, based on two proposed reduced 2-stage stochastic programming ILP models (MDVRPSRC-2S1 and MDVRPSRC-2S2). These two models are derived from the Multi Depot Vehicle Routing Problem with Stochastic Road Capacity (MDVRPSRC-2S) which is proposed next to the deterministic model of Multi Depot

Vehicle Routing Problem with Road Capacity (D-MDVRPRC) stemming from the preliminary research, prior to the development of MDDVRPSRC model. Results indicate comparable quality of solution from the proposed heuristics to that of CPLEX in random setting of the problem instances. In addition, the proposed heuristics are especially superior in computation time.

The contributions of the research are as follows: (1) The MDP model for MDDVRPSRC, deterministic D-MDVRPRC as well as 2 stage stochastic ILP MDVRPSRC-2S models are respectively developed and presented; (2) based on the MDVRPSRC-2S it is shown how 2-stage stochastic programming model can be applied through CPLEX execution during each of Monte Carlo simulated PDS - RA by proposing another two models as two reduced version (MDVRPSRC-2S1 and MDVRPSRC-2S2) of the MDVRPSRC-2S; (3) the radial tremor disaster dispersion from a single or multiple epicentres and the corresponding deterioration of road capacity distribution mean and travel time are proposed; (4) the solution algorithm: TBIH-1, and its 4 variants (TBIH-2, TBIH-3, TBIH-4 and TBIH-5) are presented; (5) test dataset is developed consists of simulated road networks and the damage unit of each roads due to the earthquake for experimentation and simulation purposes, and finally (6) a decision support system (MDDVRPSRC DSS) for simulating online delivery operation during disaster is designed. All of these could be applied to all types of dynamic vehicle routing problem involving any types of disaster and its inherent stochastic road capacity as well as increased delayed travel time.

Abstrak tesis yang dikemukakan kepada Senat Universiti Putra Malaysia sebagai memenuhi keperluan untuk ijazah Doktor Falsafah

**PERMASALAHAN NAVIGASI KENDERAAN DINAMIK PELBAGAI
GUDANG MELIBATKAN KAPASITI JALAN YANG RAWAK UNTUK
PENGHANTARAN BEKALAN PERUBATAN KECEMASAN DI DALAM
LOGISTIK KEMANUSIAN**

Oleh

WADI KHALID BIN ANUAR

Pengerusi : Lee Lai Soon, PhD
Institut : Penyelidikan Matematik

Sebagai sebahagian daripada kajian logistik kemanusiaan untuk penghantaran bekalan perubatan kecemasan ketika bencana alam, model and penyelesaian kepada Masalah Navigasi Kenderaan Berbilang-Gudang Dinamik melibatkan Kapasiti Jalan yang Rawak telah dikemukakan. Berdasarkan keadaan gawat ketika musibah alam, model dan penyelesaian yang dikemukakan telah dianalisa dan dibuktikan melalui satu sistem sokongan keputusan, MDDVRPSRC DSS. Model yang dikemukakan adalah berdasarkan teori kerangka model Proses Keputusan Markov (MDP) sebagai sebahagian daripada penyelesaian pembelajaran pengukuhan. Melalui model ini, masalah berbilang objektif, berbilang gudang, berbilang perjalanan dan penghantaran secara berasingan oleh kumpulan kenderaan yang serupa telah diperhalusi. Di samping itu taburan kapasiti jalan di mana purata taburan tersebut berkurangan sepanjang tempoh operasi telah digambarkan di dalam masalah ini.

Untuk menyelesaikan model yang dicadangkan ini, kaedah Anggaran Pengatucaraan Dinamik (ADP) telah digunapakai memberi fokus kepada kaedah memandang ke hadapan. Secara khusus, algorithma Tebaran Keadaan Selepas Keputusan (PDS-Rollout (PDS-RA)) telah diadaptasikan. Lima varian daripada heuristik binaan, Heuristik Binaan Berdasarkan Pengajaran (TBIH-1 - TBIH-5) telah dikemukakan yang sesuai digunapakai bersama kaedah PDS-RA apabila diaplikasikan ketika menjalankan kaedah tebaran memandang ke hadapan melibatkan kapasiti jalan yang rawak.

Keputusan komputasi yang terhasil telah dibandingkan dengan kaedah matheuris-

tic. Dari kaedah yang novel ini, pengiraan CPLEX dilaksanakan pada setiap titik arahan tebaran berdasarkan kaedah permodelan 2 Tahap Pengaturcaraan Linear Integer Rawak (ILP) (MDVRPSRC-2S1 dan MDVRPSRC-2S2). Kedua-dua model ini dihasilkan daripada Masalah Navigasi Kenderaan Berbilang-Gudang melibatkan Kapasiti Jalan yang Rawak (MDVRPSRC-2S) yang diperkenalkan seperti juga model deterministik oleh Masalah Navigasi Kenderaan Berbilang-Gudang melibatkan Kapasiti Jalan (D-MDVRPRC) yang dihasilkan daripada kajian awal sebelum pembentukan model MDDVRPSRC. Keputusan yang terhasil menunjukkan perbandingan yang lebih kurang setara diantara heuristik-heuristik yang diperkenalkan dan matheuristic tersebut di dalam keadaan rawak yang terdapat pada koleksi ujian. Tambahan lagi, heuristik-heuristik yang diperkenalkan adalah lebih baik berdasarkan masa pengiraan pengkomputeran yang diperlukan.

Sumbangan kajian ini adalah seperti berikut: (1) MDP model untuk MDDVRPSRC, deterministik D-MDVRPRC dan juga 2 Tahap Rawak ILP MDVRPSRC-2S model telah diperkenalkan; (2) berdasarkan MDVRPSRC-2S yang diperkenalkan, kajian menunjukkan bagaimana CPLEX boleh dilancarkan pada setiap simulasi Monte Carlo di dalam PDS-RA dengan memperkenalkan pula dua varian model (MDVRPSRC-2S1 dan MDVRPSRC-2S2) daripada model MDVRPSRC-2S; (3) taburan bulatan gegaran daripada satu atau lebih punca gempa bumi dan pengurangan purata taburan kapasiti jalan raya serta masa perjalanan telah diperkenalkan; (4) algorithm penyelesaian: TBIH-1 dan empat variannya (TBIH-2, TBIH-3, TBIH-4 dan TBIH-5) telah diperkenalkan; (5) data ujian telah dibangunkan terdiri daripada simulasi rangkaian jalan raya dan unit kerosakan jalan berpunca daripada gempa bumi untuk tujuan eksperimen dan simulasi; dan akhirnya (6) sebuah sistem sokongan keputusan (MDDVRPSRC DSS) untuk tujuan simulasi penghantaran bekalan ketika bencana telah dibangunkan. Kesemua sumbangan ini boleh diaplikasikan untuk semua jenis permasalahan navigasi kenderaan yang dinamik melibatkan bencana dan kapasiti jalan yang rawak yang terkesan serta kelewatan perjalanan masa yang bertambah.

ACKNOWLEDGEMENTS

My sincere and utmost gratitude to the All Mighty, Most Compassionate, Most Merciful Allah SWT Who has always been supporting me against the insurmountable odds, Who has always been bestowing me with knowledge, comprehension and ideas to keep me steady throughout my research path.

My family especially my father and mother and also my wife who has been there supporting me and accompanying me along this journey with their prayers and positive encouragements. My sincere appreciation to my research supervisor Prof. Dr. Lee Lai Soon, who has been guiding me throughout the research and publications while also managing the research funds, providing research tools for me as well as inviting me in his research circle. Not forgetting Prof. Dr. Stefan Pickle, Prof. Dr. Maximilian Moll, the late Assoc. Prof. Dr. Bakri Adam as well as Prof. Dr. Leong Wah June for their supports in my research.

My appreciation must also without doubt goes to Universiti Utara Malaysia (UUM) in supporting my career as a tutor while pursuing my PhD degree. In the same manner Universiti Putra Malaysia has also been aiding me with my research from day one with all the facilities and supports as well as knowledge that it has to offer as a public learning institution. Especially the Geran Putra-Inisiatif Putra Siswazah (GP-IPS/2017/9579500) which has been funding me with my research. I also extend my heartfelt appreciation to Institute for Mathematical Research (INSPEM), lead by Prof. Dr. Muhammad Rezal Kamel Ariffin, as the institution for my research with Dr. Nur Sumirah Mohd. Dom as my PhD coordinator. Last but not least Pn. Noor Suhana Mohd Azahari, Pn. Zahratun Nur Yosminar and all INSPEM staffs, researchers and fellow research students who has been supporting me.

In the spirit of honouring the MoU between Universiti Putra Malaysia (UPM) and Universität der Bundeswehr München (UniBw Munich), Prof. Dr. Lee Lai Soon (representing INSPEM), Prof. Dr. Stefan Pickl from UBw Munich as well as myself (representing both Institute for Mathematical Research (INSPEM, UPM) and Universiti Utara Malaysia (UUM)) set out to collaborate on research looking into the Machine Learning approach in dealing with the multi depot dynamic vehicle routing problem with stochastic road capacity for the application of Humanitarian Logistics. Our many discussions leads to the idea of applying for the German Academic Exchange Service (DAAD) Research Grants - Bi-nationally Supervised Doctoral Degrees, (2018/19 (57381333)) in enabling research attachment for me as an exchange postgraduate student in Munich. Without the crucial funding for the research collaboration, this collaboration would not have been possible.

I certify that a Thesis Examination Committee has met on 17 June 2022 to conduct the final examination of WADI KHALID BIN ANUAR on his thesis entitled "MULTI DEPOT DYNAMIC VEHICLE ROUTING PROBLEM WITH STOCHASTIC ROAD CAPACITY FOR EMERGENCY MEDICAL SUPPLY DELIVERY IN HUMANITARIAN LOGISTICS" in accordance with the Universities and University Colleges Act 1971 and the Constitution of the Universiti Putra Malaysia [P.U.(A) 106] 15 March 1998. The Committee recommends that the student be awarded the Doctor of Philosophy.

Members of the Thesis Examination Committee were as follows:

Norazak bin Senu, Ph.D.

Associate Professor
Institute for Mathematical Research (INSPEM)
Universiti Putra Malaysia
(Chairperson)

Norihan binti Md Arifin, Ph.D.

Professor
Institute for Mathematical Research (INSPEM)
Universiti Putra Malaysia
(Internal Examiner)

Zanariah binti Abdul Majid, Ph.D.

Professor
Institute for Mathematical Research (INSPEM)
Universiti Putra Malaysia
(Internal Examiner)

Wolfgang Bein, Ph.D.

Professor
Department of Computer Science
University of Nevada, Las Vegas, USA
(External Examiner)

ZURIATI AHMAD ZULKARNAIN, Ph.D.

Professor and Deputy Dean
School of Graduate Studies
Universiti Putra Malaysia

Date:

This thesis was submitted to the Senate of Universiti Putra Malaysia and has been accepted as fulfilment of the requirement for the degree of Doctor of Philosophy. The members of the Supervisory Committee were as follows:

Lee Lai Soon, PhD

F.75	Results of Total Travel Time with M Vehicles (D4N30S10) 1: Simulated Data with 10 Measurements for each Base Heuristic	414
F.76	Results of Total Travel Time (min) with M Vehicles (D4N30S10) 2: Descriptive Analysis	415
F.77	Results of Total Computation Time with M Vehicles (D4N30S10) 1: Simulated Data with 10 Measurements for each Base Heuristic	416
F.78	Results of Total Computation Time (sec) with M Vehicles (D4N30S10) 2: Descriptive Analysis	417
F.79	Results of Average Decision Computation Time with M Vehicles (D4N30S10) 1: Simulated Data with 10 Measurements for each Base Heuristic	418
F.80	Average Decision Computation Time (sec) with M Vehicles (D4N30S10) 2: Descriptive Analysis	419
G.1	PDS_RA Performance with TBIH-1 Application as Base Heuristic	420
G.2	PDS_RA Performance with TBIH-2 Application as Base Heuristic	421
G.3	PDS_RA Performance with TBIH-3 Application as Base Heuristic	422

G.4	PDS_RA Performance with TBIH-4 Application as Base Heuristic	423
G.5	PDS_RA Performance with TBIH-5 Application as Base Heuristic	424
G.6	PDS_RA Performance with CPLEX Application as Base Heuristic	425

LIST OF FIGURES

Figure	Page
1.1 ML as the Subfield of Computer Science, Data Science and AI	4
1.2 Illustration of State Space and its Variables	6
1.3 Deterministic Trajectory and Stochastic Trajectory	7
1.4 A Portion of MDP Tree Involving Deterministic and Stochastic Transitions	9
1.5 MDP Complete Tree Involving Deterministic and Stochastic Transitions	10
1.6 MDP Components and the Interaction with the Environment	11
1.7 Conventional MDP structure: Current state & next state 1	14
1.8 Conventional MDP structure: Current state & next state 2	15
1.9 Conventional MDP structure: Current state & next state 3	15
1.10 Brief History of Post Decision State in Relation of this Research	18
1.11 PDS in MDP Structure	19
1.12 Computing Value of PDS	20
1.13 Value Computation Based on Value of PDS	20
1.14 Optimal Value Computation through PDS	21
1.15 Basic ADP Algorithm	23
1.16 Generic ADP Algorithm	24
1.17 Comparison between PDS-RA (b) and Conventional Rollout (a)	30
1.18 Research Scope	33
1.19 Research Objectives on Modelling Aspect	38
1.20 Research Objectives on Solution Aspect	39
1.21 Research Objectives on Decision Support System Aspect	39
1.22 Research Contributions based on Research Components	41
3.1 Damage Determination based on Interception on Edge due to Dispersion Radial Circle Representing Earthquake Tremor.	124
5.1 Proposed Mathuristic Rollout Concept for One Monte Carlo Episode.	156

5.2	Performing DSIH in TBIH-2 in an Example Network (a) with Node 0 as Current Position of Vehicle m and Node S9 as an emergency shelter. The potential seeds j are considered in (b) and chosen randomly in (c). As a result, node 5 (v) is inserted and route (0–5–3) is constructed.	164
5.3	Concept of Savings Algorithm	166
5.4	Performing DCW in TBIH-3 in an Example Network (a) with Node 3 as Current Position of Vehicle m and Node S2 as an emergency shelter. The Components for Performing CW is Selected in (b)	167
5.5	Performing DLASIH in TBIH-4 in an Example Network (a) with Node 0 as Current Position of Vehicle m ready to serve and Node S7 as an emergency shelter. The potential seeds j are considered in (b) and Node 9 was selected since it is the neighbour of shelter S7 in (c). As a result, node 1 (v) is inserted and route (0–1–9–S7) is constructed. (c) shows two potential seeds j (Node 4 and Node 9) at which case a random selection between Node 4 and Node 9 as a seed is done.	170
5.6	Performing DLACW in TBIH-5 in an Example Network (a) with Node 3 as Current Position of Vehicle m and Node S9 as an emergency shelter. The Components for Performing CW is Selected in (b)	174
6.1	The MDDVRPSRC DSS	179
6.2	MDDVRPSRC DSS Appear as a GUI to the User	181
6.3	MDDVRPSRC DSS GUI showing live progression of delivery operation simulation.	181
6.4	MDDVRPSRC DSS: User Selection for Pre-Computed Damage File 1	183
6.5	MDDVRPSRC DSS: User Selection for Pre-Computed Damage File 2	183
6.6	MDDVRPSRC DSS: User Selection for Damages with Selected Earthquake Epicenter	184
6.7	MDDVRPSRC DSS: Autoloop allows for consecutive automatic simulations	185
6.8	MDDVRPSRC DSS: Autoloop starting point avoiding risk of overwriting existing simulation	185
6.9	MDDVRPSRC DSS: Example of consecutive automatic measurement	186

6.10	Python Class ThreadedClient with Methods, Methods called and Objects Created	188
6.11	Python Class GuiPart with Methods, Methods called and Objects Created	189
6.12	Python Class OtherThread with Methods, Methods called and Objects Created	190
6.13	Threads Operating to ensure smooth MDDVRPSRC DSS User Experience	191
6.14	Threads is Considered Parallel when Specifically Executes one after the other through Python Global Interpreter Lock (GIL) (Beazley, 2010)	192
6.15	Threads Communicating through Queues for Visual Updates	192
6.16	Flowchart of workerThread1 1	194
6.17	Flowchart of workerThread1 2	195

C.12	Changes in Road Capacity Over Time in Online Simulation and Computation.	320

E.1	Total Distance Travelled for Maximum Road Capacity Setting (6, 7, 8): Offline and Online Computation for all Instances based on Model Characteristic.	330
E.2	Total Distance Travelled for Maximum Road Capacity Setting (2, 3, 4): Offline and Online Computation for all Instances based on Model Characteristic.	330
E.3	Total Travel Time for Maximum Road Capacity Setting (6, 7, 8): Offline and Online Computation for all Instances based on Model Characteristic.	331
E.4	Total Travel Time for Maximum Road Capacity Setting (2, 3, 4): Offline and Online Computation for all Instances based on Model Characteristic.	331
E.5	Computation Time for Maximum Road Capacity Setting (6, 7, 8): Offline and Online Computation for all Instances based on Model Characteristic.	332
E.6	Computation Time for Maximum Road Capacity Setting (2, 3, 4): Offline and Online Computation for all Instances based on Model Characteristic.	332
E.7	Total Distance Travelled: Offline and Online based on Model Characteristic and Maximum Road Capacity Setting.	333
E.8	Total Travel Time: Offline and Online computation based on Model Characteristic and Maximum Road Capacity Setting.	333
E.9	Computation Time: Offline and Online computation based on Model Characteristic and Maximum Road Capacity Setting.	334
E.10	Total Distance Travelled for Maximum Road Capacity Setting (6, 7, 8) in Online and Offline Computation for all Instances grouped by Model Characteristic.	334
E.11	Total Distance Travelled for Maximum Road Capacity Setting (2, 3, 4) in Online and Offline Computation for all Instances grouped by Model Characteristic.	335
E.12	Total Travel Time for Maximum Road Capacity Setting (6, 7, 8) in Online and Offline Computation for all Instances grouped by Model Characteristic.	335
E.13	Total Travel Time for Maximum Road Capacity Setting (2, 3, 4) in Online and Offline Computation for all Instances grouped by Model Characteristic.	336
E.14	Computation Time for Maximum Road Capacity Setting (6, 7, 8) in Online and Offline Computation for all Instances grouped by Model Characteristic.	336

E.15	Computation Time for Maximum Road Capacity Setting (2, 3, 4) in Online and Offline Computation for all Instances grouped by Model Characteristic.	337
E.16	Total Distance Travelled in Online and Offline Computation for all Instances grouped by Model Characteristic and Maximum Road Capacity Setting.	337
E.17	Total Travel Time in Online and Offline Computation for all Instances grouped by Model Characteristic and Maximum Road Capacity Setting.	338
E.18	Computation Time in Online and Offline Computation for all Instances grouped by Model Characteristic and Maximum Road Capacity Setting.	338
G.1	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Average Total Distance Travelled (km) based on Test Instances.	426
G.2	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Average Total Travel Time (min) based on Test Instances.	426
G.3	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Average Total Computation Time (sec) based on Test Instances.	427
G.4	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Average Decision Computation Time (sec) based on Test Instances.	427
G.5	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Best Total Distance Travelled (km) Measured based on Test Instances.	428
G.6	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Best Total Travel Time (min) Measured based on Test Instances.	428
G.7	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Best Total Computation Time (sec) Measured based on Test Instances.	429
G.8	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Best Average Decision Computation Time (sec) Measured based on Test Instances.	429
G.9	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Travelled Distance over all Test Instances Applied (Omitting 10 Non-Benchmarked Measurement).	430

G.10	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Travel Time over all Test Instances Applied (Omitting 10 Non-Benchmarked Measurement).	430
G.11	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Computation Time over all Test Instances Applied (Omitting 10 Non-Benchmarked Measurement).	431
G.12	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Average Decision Computation Time over all Test Instances Applied (Omitting 10 Non-Benchmarked Measurement).	431
G.13	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Travelled Distance over all Test Instances Applied (Including 10 Non-Benchmarked Measurement).	432
G.14	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Travel Time over all Test Instances Applied (Including 10 Non-Benchmarked Measurement).	432
G.15	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Computation Time over all Test Instances Applied (Including 10 Non-Benchmarked Measurement).	433
G.16	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Average Decision Computation Time over all Test Instances Applied (Including 10 Non-Benchmarked Measurement).	433
G.17	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Travelled Distance in Road Network D3N8S3 (Including 10 Non-Benchmarked Measurement).	434
G.18	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Travel Time in Road Network D3N8S3 (Including 10 Non-Benchmarked Measurement).	434
G.19	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Computation Time in Road Network D3N8S3 (Including 10 Non-Benchmarked Measurement).	435

G.20	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Average Decision Computation Time in Road Network D3N8S3 (Including 10 Non-Benchmarked Measurement).	435
G.21	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Travelled Distance in Road Network D4N11S4 (Including 10 Non-Benchmarked Measurement).	436
G.22	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Travel Time in Road Network D4N11S4 (Including 10 Non-Benchmarked Measurement).	436
G.23	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Computation Time in Road Network D4N11S4 (Including 10 Non-Benchmarked Measurement).	437
G.24	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Average Decision Computation Time in Road Network D4N11S4 (Including 10 Non-Benchmarked Measurement).	437
G.25	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Travelled Distance in Road Network D5N13S5 (Including 10 Non-Benchmarked Measurement).	438
G.26	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Travel Time in Road Network D5N13S5 (Including 10 Non-Benchmarked Measurement).	438
G.27	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Computation Time in Road Network D5N13S5 (Including 10 Non-Benchmarked Measurement).	439
G.28	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Average Decision Computation Time in Road Network D5N13S5 (Including 10 Non-Benchmarked Measurement).	439
G.29	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Travelled Distance in Road Network D6N16S6 (Including 10 Non-Benchmarked Measurement).	440

G.30	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Travel Time in Road Network D6N16S6 (Including 10 Non-Benchmarked Measurement).	440
G.31	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Computation Time in Road Network D6N16S6 (Including 10 Non-Benchmarked Measurement).	441
G.32	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Average Decision Computation Time in Road Network D6N16S6 (Including 10 Non-Benchmarked Measurement).	441
G.33	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Travelled Distance in Road Network D7N18S7 (Including 10 Non-Benchmarked Measurement).	442
G.34	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Travel Time in Road Network D7N18S7 (Including 10 Non-Benchmarked Measurement).	442
G.35	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Computation Time in Road Network D7N18S7 (Including 10 Non-Benchmarked Measurement).	443
G.36	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Average Decision Computation Time in Road Network D7N18S7 (Including 10 Non-Benchmarked Measurement).	443
G.37	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Travelled Distance in Road Network D8N20S8 (Including 10 Non-Benchmarked Measurement).	444
G.38	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Travel Time in Road Network D8N20S8 (Including 10 Non-Benchmarked Measurement).	444
G.39	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Computation Time in Road Network D8N20S8 (Including 10 Non-Benchmarked Measurement).	445

G.40	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Average Decision Computation Time in Road Network D8N20S8 (Including 10 Non-Benchmarked Measurement).	445
G.41	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Travelled Distance in Road Network D8N22S9 (Including 10 Non-Benchmarked Measurement).	446
G.42	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Travel Time in Road Network D8N22S9 (Including 10 Non-Benchmarked Measurement).	446
G.43	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Computation Time in Road Network D8N22S9 (Including 10 Non-Benchmarked Measurement).	447
G.44	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Average Decision Computation Time in Road Network D8N22S9 (Including 10 Non-Benchmarked Measurement).	447
G.45	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Travelled Distance in Road Network D9N25S10 (Including 10 Non-Benchmarked Measurement).	448
G.46	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Travel Time in Road Network D9N25S10 (Including 10 Non-Benchmarked Measurement).	448
G.47	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Computation Time in Road Network D9N25S10 (Including 10 Non-Benchmarked Measurement).	449
G.48	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Average Decision Computation Time in Road Network D9N25S10 (Including 10 Non-Benchmarked Measurement).	449
G.49	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Travelled Distance in Road Network D9N30S10 (Including 10 Non-Benchmarked Measurement).	450

G.50	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Travel Time in Road Network D9N30S10 (Including 10 Non-Benchmarked Measurement).	450
G.51	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Computation Time in Road Network D9N30S10 (Including 10 Non-Benchmarked Measurement).	451
G.52	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Average Decision Computation Time in Road Network D9N30S10 (Including 10 Non-Benchmarked Measurement).	451
G.53	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Travelled Distance in Road Network D4N30S10 (Including 10 Non-Benchmarked Measurement).	452
G.54	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Travel Time in Road Network D4N30S10 (Including 10 Non-Benchmarked Measurement).	452
G.55	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Total Computation Time in Road Network D4N30S10 (Including 10 Non-Benchmarked Measurement).	453
G.56	Algorithms Performance compared to Matheuristic Rollout Applied in PDS-RA: Total BSF Measured for Average Decision Computation Time in Road Network D4N30S10 (Including 10 Non-Benchmarked Measurement).	453
G.57	TBIH-1 Performance as PDS-RA Base Heuristic: BSF Count for Total Distance Travelled over all Road Networks.	454
G.58	TBIH-2 Performance as PDS-RA Base Heuristic: BSF Count for Total Distance Travelled over all Road Networks.	454
G.59	TBIH-3 Performance as PDS-RA Base Heuristic: BSF Count for Total Distance Travelled over all Road Networks.	455
G.60	TBIH-4 Performance as PDS-RA Base Heuristic: BSF Count for Total Distance Travelled over all Road Networks.	455
G.61	TBIH-5 Performance as PDS-RA Base Heuristic: BSF Count for Total Distance Travelled over all Road Networks.	456
G.62	Matheuristic Rollout Performance as PDS-RA Base Heuristic: BSF Count for Total Distance Travelled over all Road Networks.	456

G.63	TBIH-1 Performance as PDS-RA Base Heuristic: BSF Count for Total Travel Time over all Road Networks.	457
G.64	TBIH-2 Performance as PDS-RA Base Heuristic: BSF Count for Total Travel Time over all Road Networks.	457
G.65	TBIH-3 Performance as PDS-RA Base Heuristic: BSF Count for Total Travel Time over all Road Networks.	458
G.66	TBIH-4 Performance as PDS-RA Base Heuristic: BSF Count for Total Travel Time over all Road Networks.	458
G.67	TBIH-5 Performance as PDS-RA Base Heuristic: BSF Count for Total Travel Time over all Road Networks.	459
G.68	Matheuristic Rollout Performance as PDS-RA Base Heuristic: BSF Count for Total Travel Time over all Road Networks.	459
G.69	TBIH-1 Performance as PDS-RA Base Heuristic: BSF Count for Total Computation Time over all Road Networks.	460
G.70	TBIH-2 Performance as PDS-RA Base Heuristic: BSF Count for Total Computation Time over all Road Networks.	460
G.71	TBIH-3 Performance as PDS-RA Base Heuristic: BSF Count for Total Computation Time over all Road Networks.	461
G.72	TBIH-4 Performance as PDS-RA Base Heuristic: BSF Count for Total Computation Time over all Road Networks.	461
G.73	TBIH-5 Performance as PDS-RA Base Heuristic: BSF Count for Total Computation Time over all Road Networks.	462
G.74	TBIH-1 Performance as PDS-RA Base Heuristic: BSF Count for Average Decision Computation Time over all Road Networks.	462
G.75	TBIH-2 Performance as PDS-RA Base Heuristic: BSF Count for Average Decision Computation Time over all Road Networks.	463
G.76	TBIH-3 Performance as PDS-RA Base Heuristic: BSF Count for Average Decision Computation Time over all Road Networks.	463
G.77	TBIH-4 Performance as PDS-RA Base Heuristic: BSF Count for Average Decision Computation Time over all Road Networks.	464
G.78	TBIH-5 Performance as PDS-RA Base Heuristic: BSF Count for Average Decision Computation Time over all Road Networks.	464

LIST OF ALGORITHMS

Algorithm	Page
1.1 Compute $\overline{V}_k^a(s_k^a)$	29
3.1 Pseudocode for determining damages on all edges in road network instance.	124
5.1 Compute $\overline{V}_k^a(s_k^{ak})$ (Ulmer, 2017) based on PDS-RA proposed by Goodson (2010))	152
5.2 Matheuristic Rollout (Extended from Algorithm 5.1) to Compute \widetilde{a}_m^*	154
5.3 Compute \widetilde{a}_m^* using other Base Heuristic, \mathcal{B}	155
5.4 TBIH-1 and General Structure Algorithm. (Note: $ M'_k \leq 1$ in rollout)	158
5.5 TBIH-2 (with Embedded DSIH) Algorithm	165
5.6 TBIH-3 (with Embedded DCW) Algorithm	168
5.7 TBIH-4 (with Embedded DLASIH) Algorithm	170
5.8 TBIH-5 (with Embedded DLACW) Algorithm	175

LIST OF ABBREVIATIONS

VRP	Vehicle Routing Problem
RVRP	Rich VRP
HL	Humanitarian Logistics
DM	Disaster Management
DSS	Decision Support System
ML	Machine Learning
ADP	Approximate Dynamic Programming
MDDVRPSRC	Multi Depot Dynamic Vehicle Routing Problem with Stochastic Road Capacity
MDP	Markov Decision Processes
MILP	Mixed Integer Linear Programming
SP	Stochastic Programming
SILP	Stochastic Integer Linear Programming
D-MDVRPRC	Deterministic Multi Depot VRP with Road Capacity
MDVRPSRC-2S	Two-Stage SILP Multi Depot VRP with Stochastic Road Capacity
MDVRPSRC-2S1	Reduced Model 1 (Shelter)
MDVRPSRC-2S2	Reduced Model 2 (Depot)
D	Deterministic Model, D-MDVRPRC (Offline)
S	Stochastic Model, MDVRPSRC-2S (Offline)
SDY	Stochastic & Dynamic Model (Online)
RA	Rollout Algorithm
PRE	Pre Decision State
PDS	Post Decision State
PDS-RA	Post Decision State Rollout Algorithm
TBIH	Teach Based Insertion Heuristic
TBIH-1 – TBIH-5	TBIH variants

CHAPTER 1

INTRODUCTION

1.1 Overview

The occurrence of disasters throughout the world has led to various negative impacts including famine, outbreak of diseases, poverty and loss of life among many others. Additionally, the trends towards higher frequency of disasters and the economic effects demands an immediate attention towards efficient relief operation (Motoyama, 2017). Moreover, the impact of disasters in underdeveloped and developing countries would be worse, as they are often without sufficient resources when dealing with the aftermath of disasters. For cases such as Nepal which is also

a landlocked country that recently suffered from a 7.8 magnitude Earthquake on the 25th April 2015 and lost nearly nine thousand lives due to the initial shock alone, the need for an efficient relief aid operation is even more dire (Zhao, 2016). This includes especially, urgent medical supply to the rural area and districts during the aftermath of the disaster as reflected by Sharma (2015) and Neupane (2015).

Tracing back on the details of the event it is clear that the medical supplies in landlocked country such as Nepal are mainly depended on international aids (Chauhan and Chopra, 2017). Furthermore, there were strong demands for medical supply such as vaccination that was lacking during the post disaster event. Wang et al. (2016a) stated that during the event almost 90% of local medical centres and facilities were inoperative and that surgical dressing as well as debridement were among the supplies needed. Moreover, Chauhan and Chopra (2017) also cautioned that preparations for infectious diseases outbreak should be made during the aid operation following the collapses of hygiene and sanitation facilities during the disaster. This further stressed the importance of medical supply during the disaster for landlocked countries such as Nepal. Radianti et al. (2016a) through their data collection based on twitters worldwide also mentioned the difficulties of delivering medical supply due to the regular customs that was imposed and the lack of transportations to disseminate supplies. Moreover, whichever transportation that was available had to operate under the lack of fuel supply due to the blockade of fuel by India (Hall et al., 2017). This further illustrates the strong dependency towards neighbouring countries for a landlocked country such as Nepal, which is devoid of access of sea for crude resources such as fuel. Hall et al. (2017) further stated that most of the existing medical supplies were not used as most of them were trapped under the rubbles due to the earthquakes.

In addition, Nepal as a landlocked country also suffers logistical nightmare as all

international aid rushed towards the Tribhuvan Airport acting as the only local logistical hub which also worsen the distribution of the medical supply in Nepal. The much needed upgrade of the airport were unable to host over 400 humanitarian organization supplies causing a bottleneck at the airport (Menth and Stamm, 2015). The incompatibility of the airport to cater for much larger airfreights was also among the cause of delay for medical supply in Nepal (Radianti et al., 2016a). As a result, much of the airfreight carrying significant amount of medical supplies were rerouted to neighbouring countries.

Additionally, despite large supply resources due to global aid from various nations that flooded the Kathmandu Airport during the disaster, efficient distribution of supplies are hindered due to landslides disrupting the transportation network especially the parts that lead to the rural area where medical supplies are scarce ((Radianti et al., 2016a) and (Chiaro et al., 2015)). Hall et al. (2017) for example reported on the problem of accessing remote area due to the landslides and road damages. More similar cases were mentioned such as in Okamura et al. (2015) where heavy damages sustained by the Kathmandu – Bhaktapur Road of Araniko Highway caused major disruption in medical supply. Further reports on lack of coordination in delivering aid supply would also be a strong justification for the proposed research as efficient medical supply routing would also need to integrate coordination factor into its model and solution (Hall et al., 2017). Hence the problem observed includes limited transport vehicles, congested single point of supplies collection, and uncertainties in route options as well as road facility sustaining continuous damages (Radianti et al., 2016a).

From this particular aspect, it is seen that multi depots could be the means to alleviate the bottleneck problem in Kathmandu Airport where these depots could represent a number of alternative airports. Due to the limited transport vehicle, it is hypothesized that multi trip and split delivery between vehicles when delivering to specific destination could be useful. Similarly there is an obvious correlation between the disaster strike zone and the ongoing disruption of road network which necessitate dynamic update as a means to tackle the uncertainties.

Motivated by these observations, a Multi Depot Dynamic Vehicle Routing Problem with Stochastic Road Capacity (MDDVRPSRC) is proposed and presented. Furthermore prior investigation to the development of MDDVRPSRC has lead to the development of the Deterministic Multi Depot Vehicle Routing Problem with Road Capacity (D-MDVRPRC) model, the two-stage Stochastic Integer Linear Programming (SILP) Multi Depot Vehicle Routing with Stochastic Road Capacity (MDVRPSRC-2S) model, as well as two reduced models of MDVRPSRC-2S: MDVRPSRC-2S1 and MDVRPSRC-2S2 that can be applied iteratively to solve the MDDVRPSRC in a dynamic manner. As a result, a novel matheuristic rollout is also presented.

In addition, inspired by the work of Goodson et al. (2013), Novoa and Storer (2009) and many others whose application is more geared towards industry and commercial purposes, this research aims to expand further from the conventional Machine Learning (ML) approach in VRP of clustering the vehicle first, as part of the measure in dealing with the vast action space. Fresh approach is needed for problem where the clustering of vehicles might not be applicable due to the stochastic road capacity within the transport network. Furthermore, with the entry level machine available for the research, the Monte Carlo simulations and the lookahead horizon needed must be limited yet a good decision must be computed. Normally, this is a contradiction within the field of VRP adopting Rollout Algorithm (RA) in the scope of Reinforcement Learning (RL). This contradiction however is addressed by proposing individual computation of decision for each vehicle as opposed to computing decision collectively.

This research is differentiated further through the presentation of models that adapts to the changing of road capacity. Here, different base heuristics are proposed and applied in the Post Decision State Rollout Algorithm (PDS-RA) advocated by Goodson et al. (2013) that could be more suitable to tackle specific problem of deteriorating and stochastic road capacity. The base heuristics presented are then compared with the matheuristic rollout through which a new test dataset is introduced. Moreover, the tremor of the earthquake is also simulated through which the deteriorating damage and capacity of roads are anticipated and considered. Finally, an MDDVRPSRC Decision Support System (DSS) is presented as a simulation platform to support decision making for the case of MDDVRPSRC while also aiding the simulated data collection for validation and performance benchmark.

1.2 Research Background

This section served as a quick introduction to the core components of the research. The field of VRP and its inherent solution algorithm is vast and is considered known to the reader. To those uninitiated in VRP, the textbooks by Toth and Vigo (2002) and Toth and Vigo (2014) are referred. Additionally, to those interested to learn the basics of heuristic and metaheuristic, the textbooks by Labadie et al. (2016) and Talbi (2009) are also referred.

Full focus is given instead on Machine Learning (ML), Reinforcement Learning (RL) the solution of RL with regards to Approximate Dynamic Programming (ADP), as well as the lookahead approach in ADP as these fields represents the core of this research where every contributions are made towards modelling and solving the MDDVRPSRC for emergency delivery as part of the humanitarian operations in HL.

This chapter starts off with the general overview of ML and later zoom into the RL through the description of Markov Decision Processes (MDP), the solution methodology of MDP, the curse of dimensionality as well as the extended framework of MDP modelling involving Post Decision State (PDS) structure. The discussion on the curse of dimensionality leads to the topic of ADP. From ADP, the focus quickly narrows down into the lookahead approach where the Rollout Algorithm (RA) is described in detail. Finally the extended version of RA (PDS-RA) which is the core solution of MDDVRPSRC is explained.

1.2.1 Machine Learning, Reinforcement Learning and Markov Decision Processes

It is quite rare to talk about optimization or OR together with ML as they are treated as different entities branching on their own fields. However, recent trend in the literatures proves that this might no longer be the case. Various OR problems including VRPs are already addressed based on the ML approach specifically in RL. Future trend seems to point towards hybridization of ML and other classical optimization approaches such as metaheuristic, heuristic, and exact solution algorithms.

ML is the subfield of artificial intelligence (Figure 1.1) which is the subfield of computer science (Theobald, 2017). The aim of ML is to allow machine in the form of programs or codes to learn by itself the task that is required of them instead of the programmer having to tell them what to do. In fact, we now see programmers collecting data and feeding them into the learning model and algorithm leaving the ML code to organize and act based on the prediction made through its learning process (Alpaydin, 2016).

Figure 1.1: ML as the Subfield of Computer Science, Data Science and AI
[Source: Theobald, 2017]

Depending on the nature of learning, the ML is divided further into three categories (Theobald, 2017):

1. Supervised Learning,
2. Unsupervised Learning, and
3. Reinforcement Learning.

Despite the fact that there are three categories in ML, it is interesting to note that RL is adopted most for solving Complex Optimisation Problems (COPs). Such literatures includes Nadi and Edrisi (2017) and Keneally et al. (2016) where complex VRPs are addressed in times of disasters. On the other hand, few literatures are also seen adopting unsupervised learning through the Fuzzy C Means (FCM) variants such as in Ruan et al. (2016). Recently James et al. (2019) applied deep neural network, a supervised learning approach, in generating vehicle route online, while Zhang et al. (2020) applied multi agent RL in dealing with the VRP.

1.2.2 Markov Decision Processes

The core of this research is the Markov Decision Processes (MDPs) which is the prerequisite modelling framework to RL. It provides the modelling framework that represents RL given in:

- State, s_k in the state space S :
 - comprised of initial state s_0 , the end or termination state s_K .
 - each state observable by the agent at decision epoch k at time t .
- Decision of action, a_k in the action space A :
 - at each decision epoch k , selection of action in action space is possible: $a_k \in A(s_k) \subset A$ where A is an action space consist of all available actions for all states available.
- Reward model, $R(s_k, a_k)$.
- Transition model:
 - deterministic transition model: $s_{k+1} = S^M(s_k, a_k)$.
 - stochastic transition model: $s_{k+1} = S^M(s_k, a_k, W_{k+1})$.

In this modelling framework, the state s_k represents a snapshot at decision epoch k of what is observed by an agent of a certain environment as opposed to how a human being would perceived an environment. It is deemed as limited as normally what is observable to a machine is limited to their sensory inputs and data transfer size. Different sensory inputs that are accessible to an agent are represented by

different state variables. Therefore, an observation (state) made by an agent consist of a multidimensional vectors of variable values depending on what is observed by the agents. This observation is made by the agent at time t or decision point k , where agent is require to make a decision or take an action a_k . For example, in a specific point of time t where an agent needs to make a decision in a VRP, a state s_k might be represented by a number of unserved customers c , capacity status of each delivery vehicles q and demands of unserved customers d as it state's variable.

What is observed by the agent is then:

$$s_k = [c, \mathbf{q}, \mathbf{d}], \quad (1.1)$$

which is a multidimensional vector of specific state that could be represented as in Figure 1.2. The state space is then the space confined by the range of all variable axis c, \mathbf{q} and \mathbf{d} where all different points of s_k exists. A simple state is assumed by having c as an integer variable with \mathbf{d} and \mathbf{q} as a vector of n customer demands $d \in \{0, 1\}^n$ and capacity of vehicles $\mathbf{q} \in \{0, 50\}^{|M|}$ for vehicle $m \in M$. However, each value of variable may yet be another vector which extends the axis further enlarging the state space by the length of the axis. Action a_k represents a limited or selected scope of decision or action that an agent is permitted to make or perform at a decision epoch k based on what is observed during the triggered decision epoch. Making a decision changes the environment or process and this in turns is observed by the agent further as the next state of the environment. If the environment is deterministic, where no uncertainty is concerned, the next state observed by the agent due to the action taken is denoted as:

$$s_{k+1} = S^M(s_k, a_k). \quad (1.2)$$

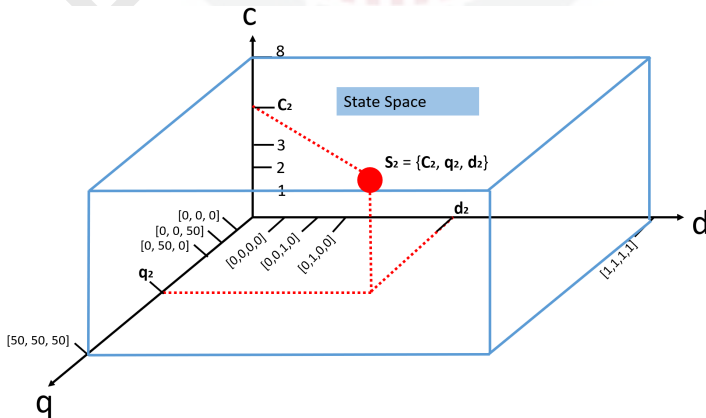

Figure 1.2: Illustration of State Space and its Variables

In MDP this is known as the deterministic transition model. When an agent has knowledge on both reward and transition model ($s_{k+1} = S^M(s_k, a_k)$), the MDP model is known as model based MDP. Alternatively a popular approach of MDP represent the environment as a black box where the agent, having no prior knowledge on rewards and transition model, could only perform an action and obtained reward in return of its action. Based only on this interaction with the black box (environment), an agent is required to compute an optimal policy by learning the transition model and reward model instinctively through series of action - reward interactions. This type of MDP model is known as the model free MDP seen applied in popular RL application such as the Atari (Mnih et al., 2013) and the Alphago Zero (Silver et al., 2017).

In a more realistic situation or environment, transition of states observed by the agents is rarely deterministic in nature. For example, if an agent make a decision to drop a leaf. In a deterministic world devoid of uncertainty elements, the agent would perceived based on the deterministic transition state of the MDP model that the leaf would fall in a vertical trajectory. However, in a realistic stochastic world, random uncertain gust of wind might influence the position of the leaf as it falls. As a result, the leaf trajectory might no longer be following a vertical line (Figure 1.3). In such a case an agent can only instead, *expect* a certain trajectory of the leaf falling based on random distribution of wind in the vicinity. An agent could only make prediction and expect such motion if the system model takes into account random information W .

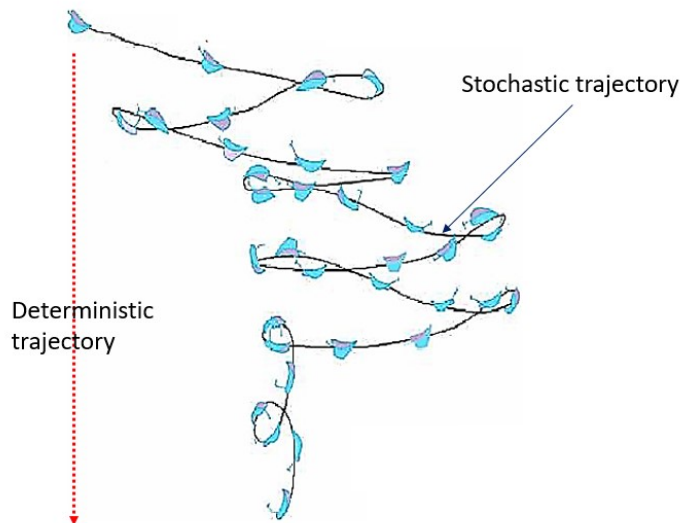

Figure 1.3: Deterministic Trajectory and Stochastic Trajectory
[Source: Haiyan, 2010]

Thus in a stochastic world, the transition model are now defined as:

$$s_{k+1} = S^M(s_k, a_k, W_{k+1}). \quad (1.3)$$

If one to reflect back on the model free MDP, such transition model is not specifically known to an agent. Instead, agent would need to sample series of an episode or realization ω by randomly performing an action and observed the transitioning state as well as the rewards obtained. An agent would need to perform random sampling each time creating a trajectory or episode ω that depends on random changes (denoted at the moment as \hat{p}) that occurred at decision epoch k at time t . As such, the random information W is depicted as $W_k(\omega_m(k))$ at decision epoch k or at time t as $W_t(\omega_m(t))$. An MDP model could consider more than one random variables hence the variable \hat{p} could instead be a vector consist of all random variable observed by the agent.

A clear example of random information could be seen in Table 1.1:

Table 1.1: Example of Trajectories of Transitions Enabled by Sampling Random Information $W_k(\omega_m(t))$

	$t = 1$	$t = 2$	$t = 3$	$t = 4$	$t = 5$	$t = 6$	$t = 7$	$t = 8$
ω	\hat{p}_1	\hat{p}_2	\hat{p}_3	\hat{p}_4	\hat{p}_5	\hat{p}_6	\hat{p}_7	\hat{p}_8
1	(-14, -26)	(7, 16)	(-10, 20)	(41, 7)	(15, -11)	(8, -29)	(-6, -50)	(13, -36)
2	(11, 33)	(-36, -50)	(-23, 0)	(3, -50)	(7, -23)	(12, -10)	(35, 46)	(-18, -10)
3	(-50, -12)	(-2, -18)	(-15, 12)	(-31, 3)	(5, -2)	(-24, 33)	(10, 2)	(38, -19)
4	(1, -13)	(41, 20)	(-32, -2)	(3, -4)	(-46, 34)	(-15, 14)	(38, 16)	(48, -49)
5	(2, -34)	(-24, 34)	(-9, 25)	(-19, -40)	(1, -28)	(34, -7)	(36, -3)	(46, -35)
6	(41, -49)	(-24, -33)	(-5, -25)	(16, 36)	(8, 47)	(-17, -4)	(-29, 45)	(-48, -30)
7	(44, 37)	(7, -19)	(49, -40)	(-13, 5)	(38, 37)	(-30, 45)	(-48, -47)	(19, 41)
8	(-19, 37)	(-50, -35)	(-28, 32)	(-13, -17)	(2, -2)	(-10, -22)	(-2, 47)	(2, -24)
9	(-13, 48)	(-48, 25)	(-37, 39)	(-2, 30)	(-28, 33)	(-35, -49)	(-44, -13)	(-6, -18)
10	(48, 5)	(37, -39)	(43, 34)	(-13, -6)	(28, -37)	(-47, -12)	(13, 28)	(26, -35)

[Source: Powell, 2007]

From the table it could be seen that 10 samples of realization or episodes from decision epoch 1 ($k = 1$) to decision epoch 8 ($k = 8$), where each time random transition occurred and random information W_k is known. For example in the 10th sample or episode, at decision point $k = 5$ two random parameters are known ($\hat{p}_5 = \{28, -37\}$) and are then observed by the agent. Hence, at that decision point ($k = 5$) of the 10th sample random information $W_5(\omega_{10}(5)) = \hat{p}_5 = \{28, -37\}$ is obtained by sampling. The agent next observed from the environment a new state (s_{k+1}) (as modelled by Equation (1.3)) based on it's previous observation (s_k) and it's respective action (a_k) towards the observation as well as incoming random information (W_k).

With all the important components of MDPs being introduced, an MDPs tree depicting clear deterministic and stochastic transition are shown in Figure 1.4

and Figure 1.5, respectively. The concept of Post Decision State (PDS) is not yet discussed although it is shown in the figures as circles. At this point, the illustration of PDS is needed to mark the point of when random information is received. It could be seen from both Figure 1.4 and Figure 1.5 that agent performing action causes deterministic transition and incoming random information are observed next changing the trajectory of the transition into an uncertain stochastic transition (dashed lines).

Figure 1.4: A Portion of MDP Tree Involving Deterministic and Stochastic Transitions

[Source: Goodson, 2010]

Reward on the other hand is a feedback obtained by the agent after performing an action or making a decision. Reward usually reflects good or bad decision or action performed by the agent. This is akin to a child getting a praise for saying thank you instead of a scolding for saying anything rude. A complex and effective learning process such as MDP considers long term collected rewards as opposed to immediate short term rewards to ensure that good planning over a longer horizon or time frame.

In RL the agent might already have a knowledge of what is good and what is bad (or specifically the reward of performing an action) given a state that it observed. This is usually specified by a human via lookup table of action - reward or state-reward mapping. This concept of RL could be further understood by the following in Figure 1.6 that shows the relationship between the components of MDPs or RL. In MDPs

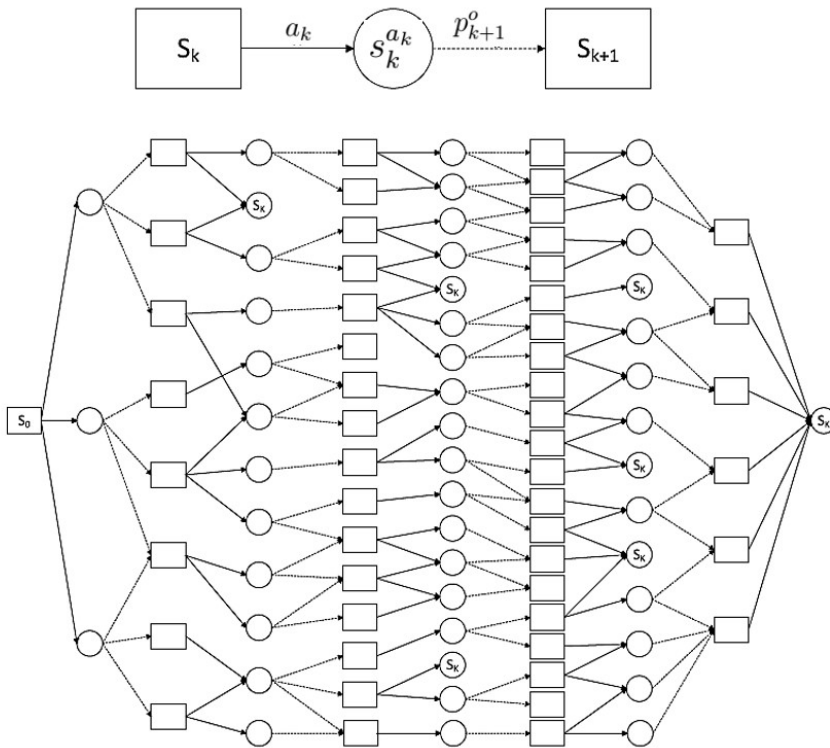

Figure 1.5: MDP Complete Tree Involving Deterministic and Stochastic Transitions

[Source: Ulmer, 2017]

or RL, an agent learns by observing a state of an environment. It then performs supposedly intelligent (computed offline or online) action. This action influence the environment and therefore changes the earlier state into a new observable state via state transition. Furthermore by performing an action, it receives a reward or incurred a cost in the form of a certain value.

The aim for an agent is to either maximize the collective rewards or to reduce the collective cost. By doing so, an agent is said to have optimized an operation (the environment model being the operation). It thus follows that to obtain the maximum sum of rewards as an indication of an optimized operation in RL, an agent would need to take the best or optimal action at each state that it observed where decision making is needed. This is achievable if an agent has a lookup table that maps each state to an optimal action it should take. This lookup table is what is known as the optimal decision rule based on an optimal policy in RL problem. Therefore, solving MDP model or problem means searching for an optimal policy to obtain an optimal decision rule.

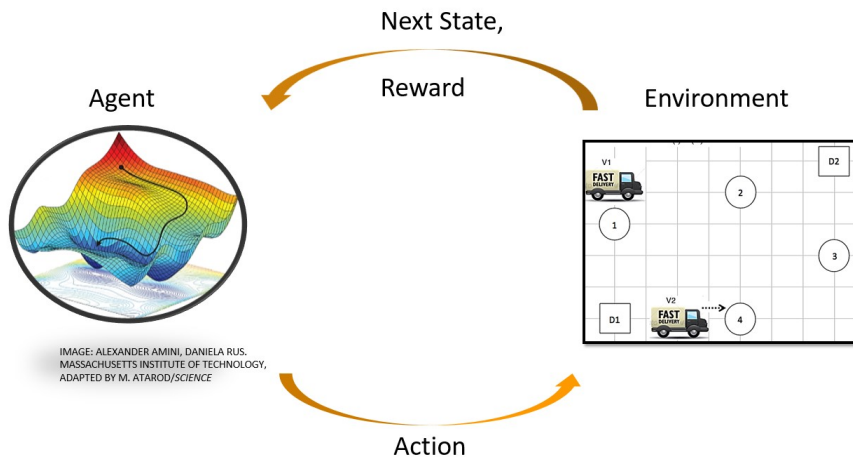

Figure 1.6: MDP Components and the Interaction with the Environment

1.2.3 Solving Markov Decision Processes

In Section 1.2.2, a brief concept of RL followed by MDPs is introduced. It is also understood that in order to solve a COPs through ML or specifically RL approach, one would have to solve for the optimal policy that would dictate an optimal decision rule.

The question would then follow:

1. *How does an agent compute the best action taken for each state that it observed ?*
2. *What measurement or parameter serves as a basis in choosing the optimal action ?*

In fact, the answer to these two questions have long been answered by Richard E. Bellman. Rightly known as the father of dynamic programming, Richard E. Bellman not only came out with the concept of solving problem through learning processes (Dreyfus, 2002), but also developed the modelling framework that we now know as MDPs (Bellman, 1957). Furthermore, he theorized the solution principle known as the Principal of Optimality (Bellman et al., 1954). All of the aforementioned contributions of Richard E. Bellman are applied in this research. The solution principal then leads to another of his contribution known as the *Bellman Equation*. Incidentally he also coined the term "*the curse of dimensionality*" which is discussed in Section 1.2.3.1 paving way to the Approximate Dynamic Programming (ADP) (Section 1.2.4) as well as the Post Decision State (PDS) (Section 1.2.3.2).

Following Bellman's Principal of Optimality, it is stated that an action taken from the initial state onwards needs to be a consistently optimal action for one to form an optimal trajectory (initial state to the end state) or episodes. This is akin to saying that for a process to be an optimal process, every decision made throughout the process from the start towards the end needs to be a series of consecutively optimal decisions. This is none other the aforementioned optimal decision rule. Another important point from this principle is that solving the optimisation problem can now be done recursively via backward dynamic programming which lands Richard Bellman the nickname, father of the dynamic programming.

The Principal of Optimality leads to both question 1 and 2 above. These questions are then answered through the Bellman Equation presented in Bellman et al. (1954). The idea of this equation is to lead the agent into choosing an action based on a value assigned to each state associated by the action taken. Conventionally, a brute force algorithm is designed for the agent to compute the values for all possible state in the state space of the environment. Once this is computed, an agent needs only to navigate itself from the initial state to the end state, each time choosing an action that it now know would lead to the next state holding the highest state's value at each decision epoch. The resulting transition of state - action - next state cycle in the navigation path until the end state, is the optimal trajectories. An objective of an agent guided by this optimal policy is thus defined as:

$$\max_{\pi \in \Pi} (\mathbb{E} \{ \sum_{k=0}^K R(s_k, A^\pi(s_k)) \}). \quad (1.4)$$

It needs to be noted here that some literatures define policy as the decision rule itself. Although the definition of policy and decision rule are in the literature commonly intertwined with one another and sometimes even used interchangeably, their difference is made clear in this research. In this research, the policy is regarded as the theme in which a decision rule is based on. For example, capitalism could be a policy in making a business decision in general but do not dictate the decision rule explicitly. More specifically, in this research, a policy could be an approach of using a specific unknown theme for choosing an action, however the function mapping the state to (a supposedly good) action is not the theme itself.

Although a good decision making involves considering long term rewards, sometimes one would also need to put emphasize on a shorter horizon of planning by giving more priority to immediate rewards as opposed to delayed rewards in the subsequent transitions. One may consider the problem of an agent navigating its way to an end goal. However, if the agent discovers that going through a longer path leads to more rewards collected, it might not be in a hurry to reach the goal. In fact, it might never reach the goal. To balance the long term rewards and the objective of the problem, a decay rate $\gamma \in [0, 1]$ is then introduced:

$$\max_{\pi \in \Pi} (\mathbb{E} \{ \sum_{k=0}^K \gamma^k R(s_k, A^\pi(s_k)) \}). \quad (1.5)$$

The core idea of solving MDP is to compute values for states involved at least in the transitions experienced by the agent. Ideally an agent would have to compute all values for all possible states that could exist in the state space which is known as the exact computation of the Bellman Equation.

The principal of optimality leads to the objective function and introduces the concept of computing value of states:

$$V_k(s_k) = R(s_k, a_k) + \gamma \mathbb{E} \{ \sum_{k=k+1}^K R(s_k, a_k) \}. \quad (1.6)$$

It is important to note that the role of expectation (\mathbb{E}) computation in the equations as an agent is considering a stochastic planning.

Furthermore, the equation can be further derived into a standard Bellman Equation that give birth to the concept of dynamic programming (Equation (1.7)):

$$V_k(s_k) = R(s_k, a_k) + \gamma \mathbb{E} \{ V_{k+1}(s_{k+1}) | s_k \}, \quad (1.7)$$

which is solved exactly by looping over all possible next states $s_{k+1} = s'$ from the current state s_k solving the expectation as in Equation (1.8):

$$V_k(s_k) = R(s_k, a_k) + \gamma \sum_{s' \in S} p(s' | s_k, a_k) V_{k+1}(s') | s_k. \quad (1.8)$$

Different action a_k taken leads to a different computed value. To guide the action into transitioning to the next best state as to maximize the rewards, an agent would have to compute the highest values possible for a state s_k in Equation (1.7) over all possible action a_k that can be made at decision epoch k . This is shown in Equation (1.9):

$$V_k^*(s_k) = \max_{a_k \in A(s_k)} (R(s_k, a_k) + \gamma \mathbb{E} \{ V_{k+1}(s_{k+1}) | s_k \}). \quad (1.9)$$

However, the objective for an agent is of course to compute the best decision rule $\rho(s_k)$ following the best policy π^* such that $\rho^{\pi^*} : s_k \rightarrow a_k^*$. The optimal action a_k^* can then be determined from the Bellman Equation by looping over all available

actions at decision epoch k as shown in Equation (1.10):

$$a_k^* = \arg \max_{a_k \in A(s_k)} (R(s_k, a_k) + \gamma \mathbb{E}\{V_{k+1}(s_{k+1}) | s_k\}), \quad (1.10)$$

hence solving MDP would mean to either solve for maximum value of each states as in Equation (1.9) as to guide the search for optimal action indirectly, or to solve for an optimal decision rule by computing directly the optimal action as in Equation (1.10) at each decision epoch until terminal state is reached. Both Equation (1.10) and (1.19) are the core equations that solves MDP exactly.

Meanwhile, the conventional mean of solving MDP through basic MDP framework (without PDS) is illustrated in the Figure 1.7 - 1.9 below where the random parameter \hat{p}_k is depicted through its possible random values p_k^f at decision epoch k where $f = \{1, 2\}$:

Figure 1.7: Conventional MDP structure: Current state & next state 1

Figure 1.8: Conventional MDP structure: Current state & next state 2

Figure 1.9: Conventional MDP structure: Current state & next state 3

1.2.3.1 The Curse of Dimensionality

Powell (2007) listed three curses of dimensionality in the dynamic programming which could be identified from the previous equation originated from the followings:

1. state space,
2. action space,
3. outcome space.

Without any approximation method, these three curses of dimensionality often would render the RL solution approach to be prohibitive. Most ADP approaches can be seen as solutions to solve any combination of these three curses. In short, ADP is a solution to approximate values computed to solve for MDP. For a simple

MDP problem, the three curses are manageable more so if it is a deterministic problem. However, a complex MDP problem leads to exhaustive computation due to explosion of state, action and outcome spaces.

A simple demonstration related to this research could illustrates the problem. For a complex MDP problem that revolves around 4 depots, 8 connecting nodes and 3 shelters connected by 58 edges with 3 vehicles for delivery operations, a stochastic road capacity is considered: low capacity, medium capacity, and high capacity. For the repetitive process of decision making, an agent is made to observe the following:

1. Current location of each vehicle, $l_k \in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15\}^{|M|}$.
2. Arrival time to destination of each vehicle, $t_k \in [1..300]^{|M|} \subset \mathbb{Z}$.
3. Capacity status of each vehicle, $q_k \in \{0, 50\}^{|M|}$.
4. Current occupancy of each roads associated with each vehicles, $e_k \in \{0, 1\}^{174}$.
5. Demand status of each shelter (connecting nodes and depots set to zero), $d_k \in \{0, 50, 100, 150, 200, 250, 300\}^{|D|}$.
6. Road capacity, $r_k \in \{0, 1, 2\}^{58}$.

Therefore, the state observe at each decision epoch changes according the these variables:

$$s_k = [l_k, t_k, q_k, e_k, d_k, r_k]. \quad (1.11)$$

From this problem, we see that vehicle $m \in M$ with $|M|$ and nodes, n (depots, shelters and connecting nodes) $|N| = 15$. Furthermore, there are 58 edges available that made up to $(58 \times 3 = 174)$ edges associated to each vehicles. From here, it is computed that there are roughly:

$$(15^3) \times (300^3) \times (2^3) \times ((2)^{(58 \times 3)}) \times (|D|^{15}) \times (3^{58}) = 3.9 \times 10^{104} = |\mathcal{S}|,$$

possible states in the state space for this problem alone.

Moreover, since the agent need to constantly assigned location for each vehicle at every decision epoch k , there are $15^3 = 3375$ actions that need to be considered by the agent at each decision epoch and each action is associated further with 3 uncertainties: low, medium and high road capacity.

For an exact solution to this MDP problem, an agent would have to compute optimal action at decision epoch k through Equation (1.10) over all the values of 3.9×10^{104} states in the state space that involve iterative looping over all 3375 actions each featuring looping over all 3 potential outcomes when also computing the expectation term.

This means that solving stochastic MDP exactly for a realistic problem is prohibitive in practice. Due to this, many solution providers would avoid adopting RL solution approach. However, there is a real interest to solve for stochastic and dynamic problem in addressing real complex problem. The advancement of computation technology sparks a new life into the adoption of RL as a solution approach for many complex problems. Special consideration however are given to the three curses of dimensionality. Hence, the proposed structure of PDS and the birth of ADP.

1.2.3.2 The Post Decision State (PDS)

As the name suggest, the idea of PDS is quite simple and intuitive. A state is the observation of the environment made by an agent during a decision epoch based on the sensory inputs available to the agent. An agent then make a decision based on the observed state and in return observed a new state. In the proposed structure of PDS, an agent is assumed to be able to make observation just as a new random information W_{k+1} arrived after making decision a_k at decision epoch k . Thus a new state (PDS), $s_k^{a_k}$ is introduced to represent an agent's observation just after a current state s_k is observed and a decision a_k is made. This state observed by the agent right before a new state s_{k+1} is observed as the new information W_{k+1} is received.

The concept of PDS went naturally right after the introduction of MDP and dynamic programming by Bellman although no one made any official mentioned on the term PDS (Powell, 2007). Instead, the first to ever use the term PDS is Bertsekas in 1997 (Van Roy et al., 1997). It was later in 2004 that PDS is described as a solution strategy by Powell and Van Roy (Powell et al., 2005). The computational benefits and detailed explanation of PDS in regards to ADP are addressed in Powell (2007). A specific reference on how rollout algorithm could be computationally improved through the introduction of PDS is then shown in Goodson (2010).

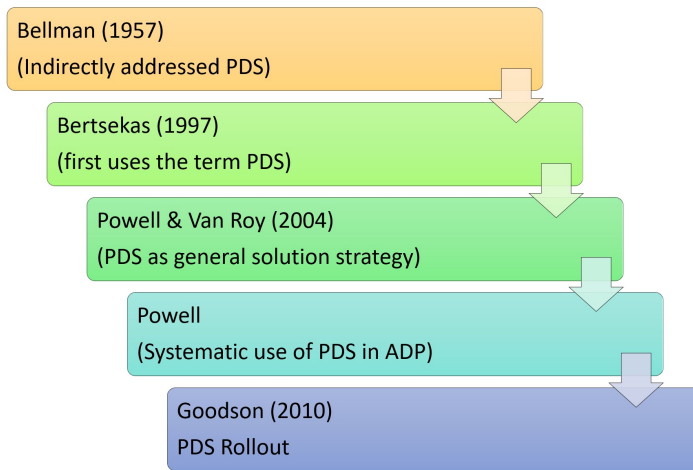

Figure 1.10: Brief History of Post Decision State in Relation of this Research
[Source: powell, 2007]

1.2.3.3 Post Decision State Structure in Markov Decision Processes

The concept of PDS is naturally embedded in MDP by dividing the transition of observation made by the agents into two: deterministic or stochastic transitions, which leads to the two observations made by the agent respectively:

1. A post decision state $s_k^{a_k}$ observed after making a decision or action a_k as a result of observing state s_k .
2. Next state s_{k+1} after random information W_{k+1} is received by the agent.

This is illustrated by the following Figure 1.4 and 1.5.

The process occurred dynamically at every decision epoch $k = 0, 1, 2, 3, \dots, K$ consist of subsequent possible actions space $A(s_k) \subset \mathbb{A}$ and random information W_{k+1} followed by all possible outcomes p_k^o of random parameter \hat{p} that could occur in the environment.

1.2.3.4 Solving Markov Decision Processes through Post Decision State Structure

In the PDS structure as explained in Powell (2007) and seen in Figure 1.5, the transition is divided into deterministic transition:

$$s_k^{a_k} = S^{(M,a)}(s_k, a_k), \quad (1.12)$$

and random transition as opposed to conventional MDP transition illustrated in Figure 1.8:

$$s_{k+1} = S^{(M,W)}(s_k^{a_k}, W_{k+1}). \quad (1.13)$$

Figure 1.11: PDS in MDP Structure

Section 1.2.3.1 presented how the curse of dimensionality in MDP model leads to prohibitive computation of values according to a standard stochastic Bellman Equation (Equation (1.9)) due to the computation of expectation term:

$$\mathbb{E}\{V_{k+1}(s')|s_k\} = \sum_{s' \in \mathcal{S}} p(s'|s_k, a_k)V_{k+1}(s'), \quad (1.14)$$

where $s_{k+1} = s'$. The computation in Equation (1.14) could be avoided thereby reducing the impact of outcome space as one of the curse of dimensionality.

The evolving Bellman's value function due to the PDS avoids computation of the expectation term. This is based on the definition of the value of the PDS which is also the expected value of the next state observed at $k+1$ decision epoch as shown in Equation (1.15):

$$V_k^{a_k}(s_k^{a_k}) = \mathbb{E}\{V_{k+1}(s_{k+1})|s_k^{a_k}\}, \quad (1.15)$$

which is further explained in Figure 1.12.

Figure 1.12: Computing Value of PDS

By substituting Equation (1.15) into the standard stochastic Bellman Equation (1.9) the expectation of next value at decision epoch $k + 1$ is then replaced by the value of resulting PDS $s_k^{a_k}$ after making decision a_k based on the observation s_k made at k . This is seen in Equation (1.16):

$$V_k^*(s_k) = \max_{a_k \in A(s_k)} (R(s_k, a_k) + \gamma V_k^{a_k}(s_k^{a_k})). \quad (1.16)$$

Figure 1.13: Value Computation Based on Value of PDS

In theory, the computation of the resulting PDS value $s_k^{a_k}$ also leads to the expectation computation as can be seen in Equation (1.15). However, this is only true for the conventional approach of solving MDP where all values need to be computed exactly. If the value of PDS $V_k^{a_k}(s_k^{a_k})$ could be approximated $\overline{V}_k^{a_k}(s_k^{a_k})$ instead of applying Equation (1.15), the computation burden in computing the expectation term could be avoided in both Equation (1.16) (as shown in Equation (1.17)) and Equation (1.15).

$$V_k^*(s_k) = \max_{a_k \in A(s_k)} (R(s_k, a_k) + \gamma \overline{V}_k^{a_k}(s_k^{a_k})). \quad (1.17)$$

Although one might argue that the value of the next state $V_{k+1}(s_{k+1})$ could also be approximated as Equation 1.18 below:

$$V_k^*(s_k) = \max_{a_k \in A(s_k)} (R(s_k, a_k) + \gamma \mathbb{E}\{\overline{V}_{k+1}(s_{k+1}) | s_k\}), \quad (1.18)$$

one would still have to deal with computing the expectation even though the values computed is now approximated. As such, the computation involving the outcome space is not avoided.

Following the same line of approach, it is also now possible through the introduction of PDS structure to compute for optimal action a_k^* guiding towards optimal decision rule $\rho^{\pi^*} : s_k \rightarrow a_k^*$ based on optimal policy applied:

$$a_k^* = \arg \max_{a_k \in A(s_k)} (R(s_k, a_k) + \gamma V_k^{a_k}(s_k^{a_k})), \quad (1.19)$$

Figure 1.14: Optimal Value Computation through PDS

as opposed to the equation below (Figure 1.9):

$$a_k^* = \arg \max_{a_k \in A(s_k)} (R(s_k, a_k) + \mathbb{E}\{\gamma^k V_{k+1}(s_{k+1}) | s_k\}). \quad (1.20)$$

Although the PDS structure provide a way to avoid computing the expectation in Bellman Equation thus relieving some of the computation burden in solving a complex MDP, one would still need to compute the value of PDS which therein lies another expectation term as is shown in Equation (1.15). In this case, ADP plays an important role of approximating the value of PDS rather than computing the value exactly through numerous method under the umbrella of ADP.

This research looks into the application of Rollout Algorithm or specifically the PDS - Rollout Algorithm (PDS-RA) as proposed by Goodson (2010) which is one of the lookahead approach in ADP.

1.2.4 Approximate Dynamic Programming

The ADP compliment the dynamic programming as a mean to deal with the curse of dimensionality that prohibit the computation of the Bellman Equation in order to solve the MDP problem. The sole idea of ADP are:

1. to avoid computing the value in Bellman Equation exactly thus avoiding oneself to deal with the exponentially vast state, action and outcome space (the three curses of dimensionality).
2. to serve as an algorithmic strategy for model free MDP.

These are achieved by moving/ stepping forward in time based on the following requirement of ADP (Powell, 2007):

- Ability to generate random samples/ episode/ trajectories:
 - Generating samples/ episodes by stepping forward in time.
 - Based on the samples, agent must learn the unknown transition model.
 - In generating episodes, random information is needed to allow for state transitions.
 - In ADP, this random information is sampled at random.
 - This is known as Monte Carlo simulation/ sampling.
- A way to make a decision:
 - Stepping forward in time involves making decision/ action as to allow forward transition from the current state onwards.

- Agent must at least has an initial rough plan on which action to take or decision to make as to create a complete trajectory (until the end state).
- In classical approach, decision is guided by value of states computed exactly by the agent.
- In ADP, these values could be approximated for obvious reason that exact computation is not possible.
- In advance and expensive method, agent is trained to recognize which state is most advantageous to move forward in time Silver et al. (2017).

By resorting to approximating values (hence the term ADP), imperfect solution is to be expected meaning that the solution would not be as good as an exact solution. However, the trade off would be the ability to solve for large and complex MDP problem. This does not mean that the approximation could be done half heartedly. In fact, this is the challenge of ADP: to approximate the value as to produce good and practical solution to the problem at hand.

The basic algorithm of ADP is given in Powell (2007):

Step 0. Initialization.

Step 0a. Initialize $\bar{V}_t^0(S_t)$ for all states S_t .

Step 0b. Choose an initial state S_0^1 .

Step 0c. Set $n = 1$.

Step 1. Choose a sample path ω^n .

Step 2. For $t = 0, 1, 2, \dots, T$ do:

Step 2a. Solve

$$\hat{v}_t^n = \max_{a_t \in \mathcal{A}_t^n} \left(C_t(S_t^n, a_t) + \gamma \sum_{s' \in \mathcal{S}} \mathbb{P}(s' | S_t^n, a_t) \bar{V}_{t+1}^{n-1}(s') \right),$$

and let a_t^n be the value of a_t that solves the maximization problem.

Step 2b. Update $\bar{V}_t^{n-1}(S_t)$ using

$$\bar{V}_t^n(S_t) = \begin{cases} \hat{v}_t^n, & S_t = S_t^n, \\ \bar{V}_t^{n-1}(S_t), & \text{otherwise.} \end{cases}$$

Step 2c. Compute $S_{t+1}^n = S^M(S_t^n, a_t^n, W_{t+1}(\omega^n))$.

Step 3. Let $n = n+1$. If $n < N$, go to step 1.

Figure 1.15: Basic ADP Algorithm

[Source: Powell, 2007]

where the similarity of the algorithm to backward dynamic programming is noted. However in this basic ADP algorithm, the computation of value is done by stepping forward in time in Step 2c (Figure 1.15). The forward transition is done through Monte Carlo sampling by randomly choosing one random information at each transition. When moving forward from the current state, an agent is said to look into the future as far as T decision point. When T is reached, one complete trajectory or one Monte Carlo simulation is said to be performed. In Figure 1.15, N Monte Carlo simulation is done to approximate the values. Prior to each trajectory or episode n , a sample path ω^n is pre-sampled in step 1 for all decision point t until T in the trajectory.

More importantly, the computation of values at Step 2a is done by the approximated value of the next state $V_{t+1}^{n-1}(s')$. It is important to note that the algorithm require only computation of state value that is transitioned as opposed to computing all state value in the state space. This substantially reduce the computation burden that is seen in the classical approach of solving MDP although it may presents the exploitation vs exploration issue. Step 2a also requires computation of expectation that maintain the burden in dealing with the outcome space. Additionally the curse of action space is also not avoided. All of these limitations is noted as the basic algorithm only served as to give an overview concept of ADP. In a more sophisticated approach of ADP, more improvements could be seen in terms of mechanism proposed in dealing with the curses of dimensionality. The output of the algorithm in Figure 1.15 is a lookup table that features computed values involve in the sampled episodes. The state which is not visited during the sampled episodes retained their initial value at Step 0a. A more generic ADP algorithm is depicted below in Figure 1.16:

- Step 0.** Given an initial state S_0^1 and value function approximations $\bar{V}_t^0(S_t)$ for all S_t and t , set $n = 1$.
- Step 1.** Choose a sample path ω^n .
- Step 2.** For $t = 0, 1, 2, \dots, T$ do:
- Step 2a. Optimization:** Compute a decision $a_t^n = A_t^n(S_t)$ and find the post-decision state $S_t^{a,n} = S^{M,a}(S_t^n, a_t^n)$.
 - Step 2b. Simulation:** Find the next pre-decision state using $S_t^n = S^M(S_t^n, a_t^n, W_{t+1}(\omega^n))$.
- Step 3.** Update the value function approximation to obtain $\bar{V}_t^n(S_t)$ for all t .
- Step 4.** If we have not met our stopping rule, let $n = n+1$ and go to step 1.

Figure 1.16: Generic ADP Algorithm

[Source: Powell, 2007]

According to Powell (2007) there are three strategies that can be used to approximate the values:

1. Lookup table approach.

2. Parametric models of value.
3. Non-parametric models of value.

This is closely related to the class of broad ADP solution approaches (Powell, 2007):

- Lookahead Approach.
- Policy Function Approximation (PFA).
- Value Function Approximation (VFA).

However in Ulmer (2017), another type of VFA is considered as a new class of solution approach:

- Lookahead Approach.
- Value Function Approximation (VFA).
- Approximate Value Iteration (AVI).

Lookahead approach such as rollout algorithm is often applied in the dynamic and stochastic MDP. The lookahead approach emphasized on the dynamic nature of the problem as the rolling horizon could be done at each decision epoch but at the cost of computation which normally needs some form of decomposition (Goodson, 2010).

On the other hand Value Function Approximation (VFA) are more common in solving complex MDP through a parametric model which is usually trained by a supervised learning as can be seen in Silver et al. (2017). The concept of VFA is to approximate the true value based on multiple basis functions based on multiple selected features or attributes important to a state. Here the attributes are akin to what is observed (normally important parameters) by the agents. A basis function is then define as $\phi_f(s_k)$. Each different features $f \in \mathcal{F}$ forms different basis functions. This features on the other hands are weighted with θ_f where the approximation of value of a state at decision epoch k can then be solved through:

$$\overline{V}(s_k) = \sum_{f \in \mathcal{F}} \theta_f \phi_f(s_k). \quad (1.21)$$

An accurate approximation might vary with the complexity of the problem. A linear regression might need less training as compared to neural network and could produce satisfying results (Ulmer, 2017). However both approaches need to be trained offline which is not desirable when one tries to execute dynamic/ online

algorithm.

In the same manner, the simplest example of Policy Function Approximation could be seen in Silver et al. (2017) where effective approximation could only be done with the state of the arts computing equipment involving countless training for the complex problem it is solving.

On the other hand, Approximate Value Iteration (AVI) make used of Monte Carlo simulation in order to generate random episodes. Once this is done, the value is updated via incremental means based on the learning rate/ step size defined by the user for the agent. The approach are similar to the general ADP algorithm presented in Figure 1.16.

1.2.4.1 Lookahead Approach - Rollout Algorithm

In relation to earlier Section 1.2.4, the lookahead approach is adopted for this research considering its suitability in terms of the requirement of live simulation as well as limitation of the hardware. Such approach allows for flexibility independent of any types of dynamic complex problem. This means that no prior training is needed to deploy the algorithm. Such is not the case with PFA or VFA that opted for parametric model approach which is normally trained offline explicitly according to the problem at hand (Silver et al., 2017). In other words, the lookahead approach could be considered as an online ADP approach as opposed to PFA and VFA which are offline ADP.

The idea of lookahead approach is to approximate the value of the state or PDS, from which the lookahead starts until the end of the lookahead horizon. Ideally the limited lookahead horizon could be expanded until the end state. However, that is normally not the case in the usual practice as the computation involved is considerably high due to the details of the problem presented in the limited time frame (Ulmer, 2017). Furthermore, decision needs to be made fast, hence computation needs to take into account how long an agent is allowed to think (compute by considering future simulations or lookahead) before making decision at each decision epoch. In the case of Alphago zero (Silver et al., 2017) for example, the agent cannot think too long before making a move in a Go game.

An extreme version of lookahead would be the tree search that considers all possible actions and all possible outcomes (Powell, 2007). When all possible outcomes are reduced to Monte Carlo sampling during the computation, the sparse sampling tree search leads to a more manageable computation. The concept is then further evolved into Rollout Algorithm which limits the tree search based on one decision and one

Monte Carlo sampling of random information per each decision epoch following a certain base policy and decision rule until the lookahead horizon ended.

The rollout is first presented in Bertsekas et al. (1997) and later applied in scheduling problem in Bertsekas and Castanon (1999). From then on further variants of rollout algorithm were introduced by Goodson (2010). Among them is the PDS - Rollout (PDS-RA) which is the solution approach applied in this research.

Conventional Rollout

The aim of rollout algorithm is to identify the optimal action or decision a_k^* at decision epoch k based on the return value $\bar{V}_{k+1}(s_{k+1})$ approximated by the rollout return $B(\pi_{\mathcal{B}(s_{k+1})}, k+1)$ where $\pi_{\mathcal{B}(s_{k+1})}$ is a certain base policy applied at a certain state s_{k+1} at decision epoch $k+1$. The standard solution to Bellman in determining optimal action a_k^* in Equation (1.10) is approximated through the approximated next state value:

$$a_k^* = \arg \max_{a \in A(s_k)} (R(s_k, a_k) + \lambda^k \mathbb{E}\{\bar{V}_{k+1}(s_{k+1})\}), \quad (1.22)$$

where $\bar{V}_{k+1}(s_{k+1})$ is approximated through rollout algorithm as the average of return of $B(\pi_{\mathcal{B}(s_{k+1})}, k+1, j)$ from decision epoch $k+1$ towards j following the decision rule $\rho^{\pi_{\mathcal{B}(s_{k+1})}}$ based on policy $\pi_{\mathcal{B}(s_{k+1})}$ that is to apply base heuristic $\mathcal{B}(s_{k+1})$:

$$B(\pi_{\mathcal{B}(s_{k+1})}, k+1, j) = \mathbb{E}^{\pi_{\mathcal{B}(s_{k+1})}} \left\{ \sum_{i=k+1}^{j-1} \lambda^{i-k+1} R(s_i, A^{\pi_{\mathcal{B}(s_{k+1})}}(s_i)) | s_{k+1} \right\}. \quad (1.23)$$

In this research the rollout is applied until the decision epoch j where $j = K$. Therefore the return is computed as:

$$B(\pi_{\mathcal{B}(s_{k+1})}, k+1) = \mathbb{E}^{\pi_{\mathcal{B}(s_{k+1})}} \left\{ \sum_{i=k+1}^{K-1} \lambda^{i-k+1} R(s_i, A^{\pi_{\mathcal{B}(s_{k+1})}}(s_i)) | s_{k+1} \right\}, \quad (1.24)$$

leaving out the j parameter in the base heuristic notation.

The rollout is executed over many Monte Carlo simulations such that different trajectories of lookahead episodes are generated. Eventually, the average return of the lookaheads performed is computed as the approximated value of the next state

$\bar{V}_{k+1}(s_{k+1})$ where, the optimal decision can be computed based on Equation (1.22).

The act of approximating value through the conventional rollout algorithm leads to a more tractable computation. However, the term expectation in Equation (1.22) still introduces extra computation based on the outcome space of the model.

By taking advantage of the PDS structure in MDP, one could further reduce the computational burden by approximating the value of respective PDS rather than the next state value via PDS-RA.

Post Decision State - Rollout Algorithm (PDS-RA)

From the previous section it can be seen that by separating the transition into deterministic (Equation (1.12)) and stochastic transition (Equation (1.13) with the value of PDS solved through Equation (1.15), one would be able to avoid computing expectation term in the standard Bellman equation by replacing the value of PDS instead of the expectations of value of the next state as in Equation (1.19).

Similarly, through ADP the exact computation PDS value is avoided by approximating it in Equation (1.25):

$$a_k^* = \arg \max_{a_k \in A(s_k)} (R(s_k, a_k) + \lambda^k \bar{V}_k^{a_k}(s_k^{a_k})), \quad (1.25)$$

with the averaged rollout return after N number of Monte Carlo Simulation for each PDS following this basic pseudo Algorithm 1.1 (Goodson, 2010):

Algorithm 1.1 Compute $\overline{V}_k^a(s_k^a)$

Input: s_k, λ, a_k
Output: $\overline{V}_k^a(s_k^a)$

```

1: Initialize  $n, k, R(s_k, a_k), B^n$ 
2:  $s_k^{a,k} = S^{M,a}(s_k, a_k)$ 
3:  $\pi_{\mathcal{B}(s_k^a)} \leftarrow \mathcal{B}(s^a)$ 
4: while  $n \leq N$  do
5:    $s^a \leftarrow s_k^a$ 
6:   while  $k \neq K$  do
7:      $R(s_k, a_k) = R(s_k, a_k) + \lambda^k R(s_k, a_k)$ 
8:      $s_k = S^{M,W}(s^a, W_{k+1}(\omega(k+1)))$ 
9:      $a_k \leftarrow A^{\pi_{\mathcal{B}(s_k^a)}}(s_k)$ 
10:     $s^a = S^{M,a}(s_k, a_k)$ 
11:     $k = k + 1$ 
12:   end while
13:    $\widehat{B}^n(\pi_{\mathcal{B}(s_k^a)}, k+1) \leftarrow R(s_k, a_k)$ 
14:    $\overline{V}_k^{a^n}(s_k^a) = \overline{V}_k^{a^{n-1}}(s_k^a) + \frac{1}{n} (\widehat{B}^n(\pi_{\mathcal{B}(s_k^a)}, k+1) - \overline{V}_k^{a^{n-1}}(s_k^a))$ 
15:    $n = n + 1$ 
16: end while
17: return  $\overline{V}_k^{a^N}(s_k^a)$ 

```

Similar to the conventional rollout, an expectation term could be seen in the Equation (1.26) below when computing the return during rollout phase:

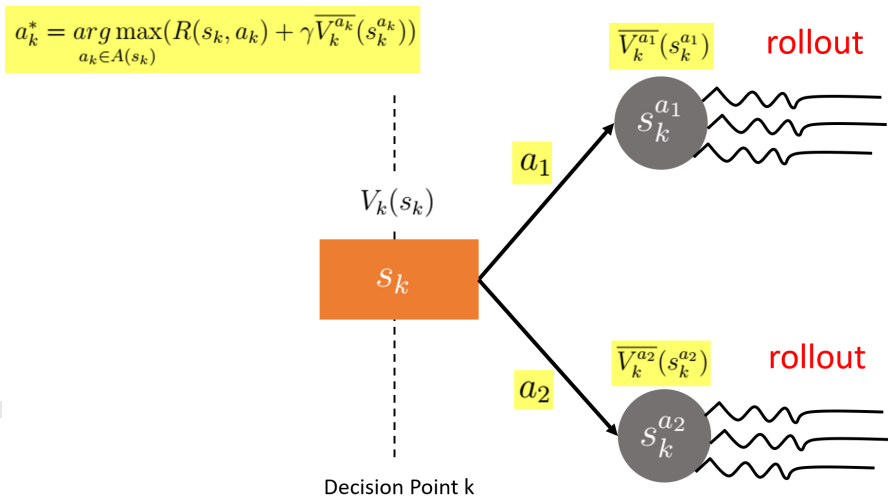

$$B(\pi_{\mathcal{B}(s_k^a)}, k+1) = \mathbb{E}^{\pi_{\mathcal{B}(s_k^a)}} \left\{ \sum_{i=k+1}^{K-1} \lambda^{i-k+1} R(s_i, a_i | s_{k+1}) | s_{k+1} \right\}, \quad (1.26)$$

However, this is only true when exact computation of the return is done by taking into consideration the large outcome space that exist in the rollout transitions. In the lookahead approach, the common approach to execute the rollout is instead to sample the stochastic variable $p_{k+1} = W_{k+1}(\omega(k+1))$ at each decision epoch $k+1$ as to allow full deterministic (through the base heuristic resulting decision rule) and stochastic (via Monte Carlo sampling) transition to generate an episode (from when the rollout is invoked to the end state s_K). This could be seen in line 8 of the Algorithm 1.1. Hence the expectation term (outcome space) is avoided when computing the Bellman Equation.

In short, the number of rollout one would have to performed is reduced when PDS-RA is applied as opposed to the conventional rollout algorithm. This is further illustrated in Figure 1.17. Meanwhile, a graphical progressions of PDS-RA are shown in Appendix A.

(a) Conventional RA

(b) PDS-RA

Figure 1.17: Comparison between PDS-RA (b) and Conventional Rollout (a)

1.3 Scope of the Research

This research can be divided into several research scopes depending on the field of which they are addressing. In this case, the research addressed simultaneously the field of Operations Research (OR), Disaster Management (DM), as well as ML. In the field of OR, the research looks into the field of humanitarian operation, a subset of Humanitarian Logistics (HL), specifically the medical supply delivery. The case of 2015 Nepal Earthquake is taken as a motivating example where the rich model MDDVRPSRC is considered and developed. The difficulties of delivering medical supply to many temporary shelters and temporary depots as an alternative to elevate the bottleneck at Kathmandu Airport is especially addressed in this research. Furthermore, the route towards these shelters could be obstructed due to the damage sustained during the Earthquake. In addressing this, a stochastic road capacity problem with progressive decrease (dynamic) of road capacity mean in the road capacity distribution depending on the tremor of the earthquakes is proposed. To this end, a simulation of earthquake tremor is also developed to model the tremor radially dispersed where the interceptions of the roads (edges) and the radial tremor lines could be translated as the damage unit sustained on the respective roads. Since both time and cost are of importance in this humanitarian problem, a multi-objectives problem is thus considered. Moreover, split deliveries and multi trip operation are also depicted in this model to ease the delivery attempt to shelters considering the limited transportation available as well as the uncertainties that plagued the delivery operation.

The DM consists of four phases namely, the preparedness, mitigation, response, and recovery phase are addressed in the research. Here the scope is narrowed down into the preparedness and response phase of DM. In the response phase, the medical supply is delivered efficiently through the proposed model and solution taking into the account of all the aforementioned factors in the previous paragraphs. Furthermore, this research also indirectly addressed the preparedness whereby the MDDVRPSRC DSS could be the tool for decision makers in generating simulation for many possible instances and prepare the respective routing plan in advance prior to any hazardous disaster.

Among the key components of MDDVRPSRC DSS is the agent interacting with the user and taking part in the simulation by making decision for the medical delivery operation in MDDVRPSRC based on the ML approach. In this case, the ML field is narrowed further into RL where agents is allowed to learn in making decision based on rewards instead of training the agent through supervised or unsupervised learning. Furthermore, since the model is complex which incurred the curse of dimensionality of ML, the solution approach is further specified by computing decision based on a lookahead policy. This lookahead policy leads to an approximate optimal decision for each state the agent is in, in real time by performing simulation of possible future episodes based on Monte Carlo sampling

instead of exactly solving the problem through a dynamic programming. Through the ADP solution approach, a one step approximate policy iteration or RA is performed at each Post Decision State (PDS) (known as PDS-RA algorithm) to compute an approximated value of a PDS associated to a potential decision. This involves performing lookahead into the future scenario where hypothetical decision is determined by the presented base heuristics which are compared with the novel matheuristic rollout. Finally, by weighing the computed values of PDSs associated with each potential decision, the near optimal decision is selected and applied by the agent when making real time decision.

In Figure 1.18, the specified scope of different fields covered by this research is shown.

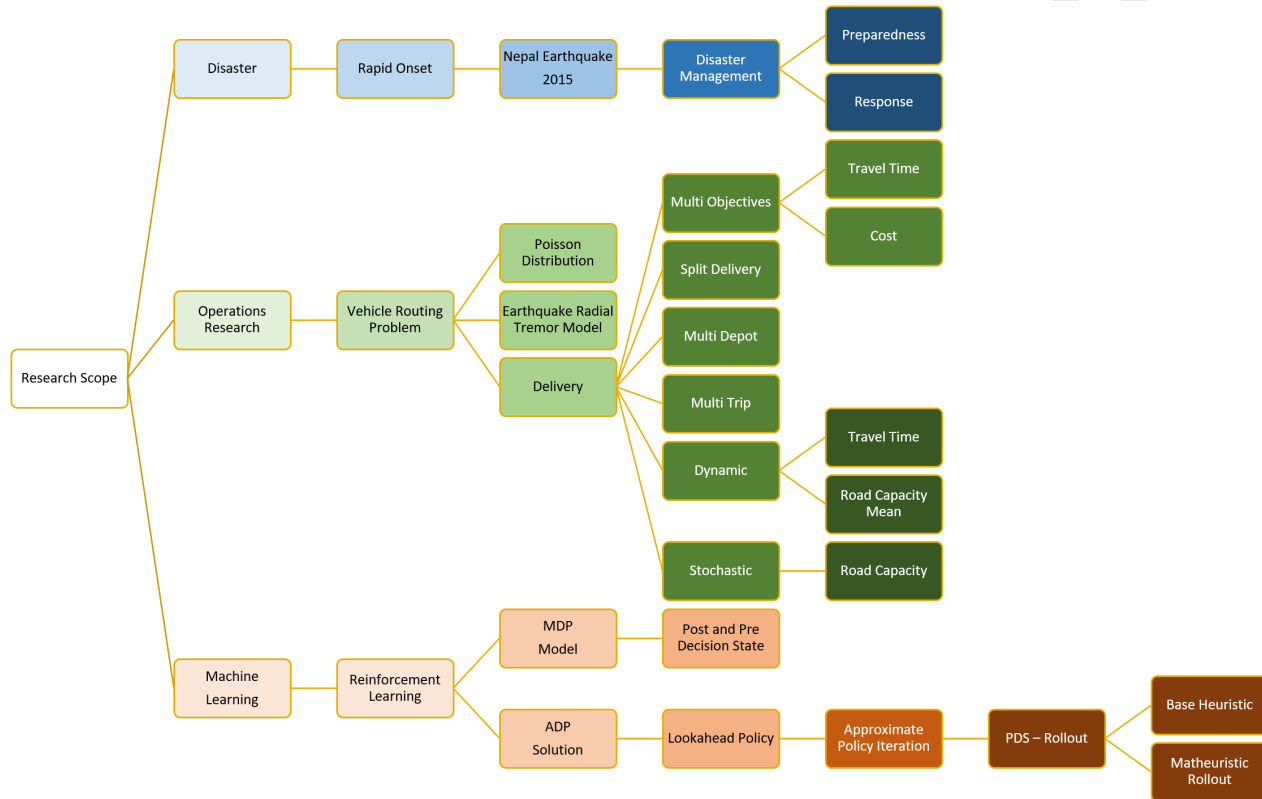

Figure 1.18: Research Scope

1.4 Problem Statements

Based on the scope of this research, the problem statement could be formulated as the followings:

1. *The vast majority of literatures that address the problem of VRP based on the approach of RL try to alleviate the curses of dimensionality through the extended framework of MDP model and ADP solution approach. The richer and more complex problem of VRP in humanitarian operations however is undoubtedly more difficult to solve which stresses further on the computation limitation at hand. Such research is therefore needed to fill the gap of VRP from the perspective of RL that address not only the application side of humanitarian operation instead of commercial problem, but also the computational challenge that comes with it.*
2. *Multiple model driven based DSS have been developed to aid with various humanitarian operation involving VRP that allow for simulation and optimization. However an intelligent DSS that react to simulated environment of such problem is still lacking. If an intelligent agent can defeat a human champion in the game of GO, it is logical for one to harness the same potential in developing an intelligent DSS that could react to the simulated environment and perform the humanitarian operation such that the results could be learned for future planning purposes.*
3. *Compared to the ever expanding solution and modelling methodology of VRP in regards to both commercial and humanitarian operations, the test dataset and benchmark development for complex and rich VRP such as those that deals with the stochastic road capacity problem is still far lacking. Most are rather outdated begging the question of their suitability in addressing modern VRPs that could also leads to the development of their respective DSS. As such, a suitable test dataset and benchmark method need to not only account for complex problem it is addressing, but also holistically flexible in ways that it could be used for the application of a DSS.*

1.5 Research Questions

Deriving from problem statements that have been formulated in Section 1.4, the research questions are listed as follows:

1. *What is the best way to optimize the medical supply delivery in a chaotic and dynamic environment that addressed the issue of stochastic road capacity and road damage in relation to the radial tremor dispersing from the disaster points of origin ?*
2. *How to model the road capacity distributions in relation to the disaster point*

of origin and the damage that the roads sustained based on their respective effects towards the operation in a realistic manner ?

3. *How to apply the ADP solution approach into a stochastic and dynamic VRP such that the curse of dimensionality is reduced and split delivery is allowed as opposed to common practices ?*
4. *How to Ireduced Monte Carlo simulations and lookahead horizon due to hardware limitation and yet able to compute good decision ?*
5. *How to perform lookahead in rollout algorithm with stochastic road capacity that render previous computed routes invalid ?*
6. *Are there any suitable test dataset and benchmark methods or solutions that can be compared with the proposed solutions ?*
7. *How to monitor the progression of the delivery operations through graphical version of the problem through simulation in order to validate the model and investigate the performance of the solutions proposed through sufficient numbers of simulation ?*
8. *Can numerous simulation be performed through a suitable interactive DSS ?*

1.6 Research Gaps

Based on these research gaps, the research questions and objectives are formed that shaped the research. These gaps could be grouped in terms of modelling aspects and solution aspects as listed below:

1. To date, very few researches address the VRP with regards to stochastic road capacity within the road network. Thus a suitable test dataset to investigate and validate this type of problem is lacking.
2. Existing VRPs that are addressed by MDP are typically less comprehensive such that most are covering problems involving only a single vehicle.
3. Models based on MDP are scarcely applied when describing rich VRP problem (RVRP) as compared to mathematical programming model such as Mixed Integer Linear Programming (MILP), Integer Linear Programming (ILP) and Stochastic Programming (SP) models.
4. Only few researches could be seen employing ML solution approach as compared to exact solution and metaheuristic solution approaches when solving the RVRP.
5. Only a number of RVRP are modelled through the structure of Pre Decision State (PRE) and Post Decision State (PDS) when modelled based on MDP model.

6. Among the researches that solved the stochastic or dynamic VRP through the ML solution approach, most applied clustering approach as a method in dealing with the curse of dimensionality of ML. To date, there is no alternative that try to approach such problem without performing clustering prior to computing the route for the case of multi vehicle operation.
7. A very limited number of RVRP are solved based on lookahead solution approach within the branch of ADP.
8. Very few within the field addressed the different base heuristics in the application of rollout algorithm.
9. It is yet to be seen the application of exact solution within the rollout as part of the dynamic base policy.
10. Only a handful of researches describe deteriorating facilities in their model when addressing VRPs in the application of humanitarian operation.
11. Among those, very few actually model the source of disruption explicitly such as the progression tremor of earthquake that leads to continuous deterioration of critical facilities such as roads and highways.

These research gaps are elaborated more in Chapter 2.

1.7 Research Objectives

This research could be separated into **four main objectives** along with their sub-objectives:

Objective 1 : to identify the rich model components of the MDDVRPSRC and to apply them in the preliminary investigation and comparison of the deterministic and stochastic version of the problem.

- 1.1 to identify the rich MDDVRPSRC model components.
- 1.2 to model the stochastic road capacity distribution that can be accessed by the MDDVRPSRC model and the 2-stage stochastic version of the model.
- 1.3 to model the radial tremor dispersion of an earthquake or any other disaster from an origin point.

Objective 2 : to enable agent to learn through RL through the development of the MDP model and to deal with the 3 curses of dimensionality based on the Extended standard framework of MDP.

- 2.1 to develop an MDP MDDVRPSRC model through the extended MDP structure that reduces the curse of dimensionality.

Objective 3 : to solve the MDDVRPSRC MDP model based on the solution approach that alleviates the 3 curses of dimensionality which also accounts for road capacity problem and the limited computation power available and to develop the corresponding benchmarking method to the solution proposed.

- 3.1 to develop an ADP solution based on the lookahead approach such that the curse of dimensionality is addressed.
- 3.2 to introduce a computing mechanism that allows for good decision computation with less Monte Carlo simulation and limited lookahead horizon.
- 3.3 to develop PDS Rollout base heuristics based on the dynamic changes of the problem and stochastic road capacity that render fixed route heuristic impractical.
- 3.4 to develop a new benchmark solution method using iterative CPLEX through a novel matheuristic rollout approach suitable for benchmarking in filling in the gap of MDDVRPSRC.

Objective 4 : to develop an MDDVRPSRC DSS with suitable features for monitoring and analysis.

- 4.1 to develop a DSS that could verify the proposed models and solutions based on a simulated test dataset.
- 4.2 to develop a DSS with an online monitoring visualization as a platform for DSS.
- 4.3 to develop a test dataset where simulated data could be compiled and comparative analysis could be performed between proposed base heuristics and the benchmark solution method.

Additionally the research objectives could also be organized based on the three core components of the research listed as follows:

- Modelling
 1. Model components identification.
 2. Model development.
- Solution
 1. Solve the specified MDDVRPSRC.
 2. Comparing performance of proposed solutions.
- Decision Support System
 1. MDDVRPSRC DSS development.
 2. Simulation and verification.

These research objectives based on the core components of the research are illustrated in Figure 1.19, Figure 1.20 and Figure 1.21 respectively.

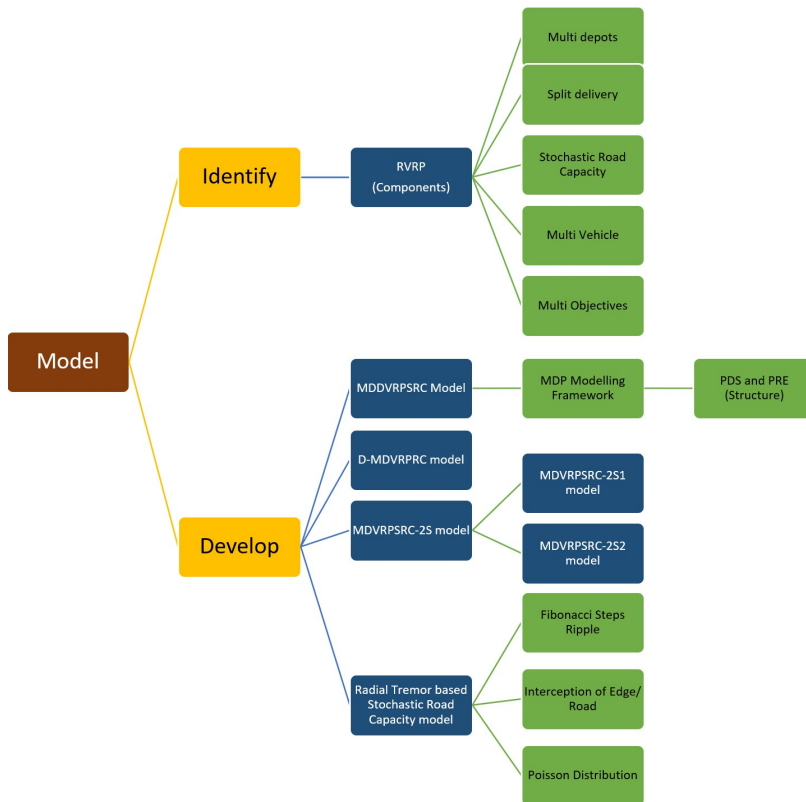

Figure 1.19: Research Objectives on Modelling Aspect

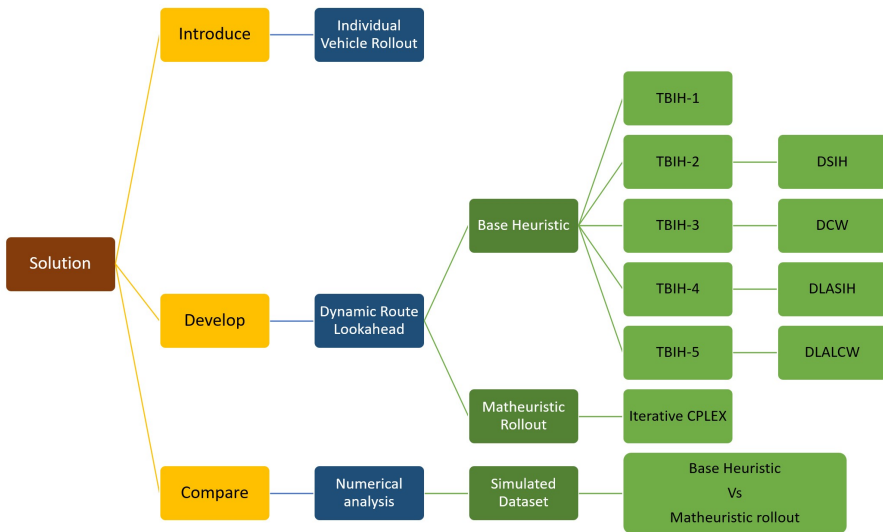

Figure 1.20: Research Objectives on Solution Aspect

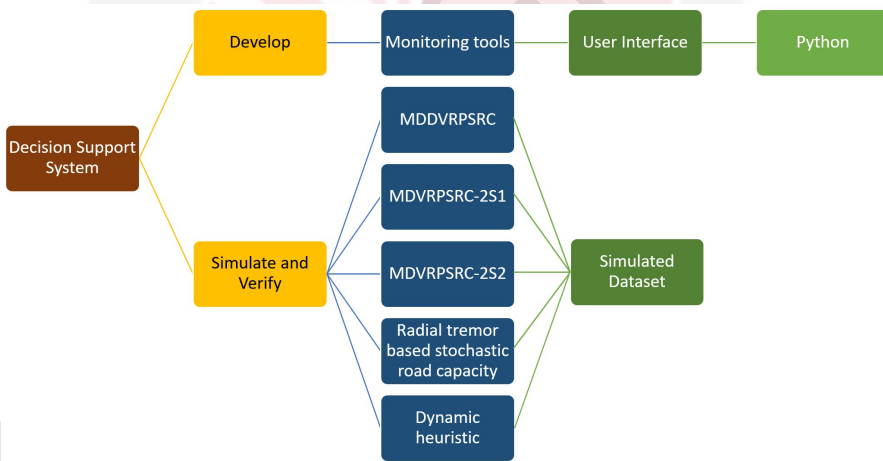

Figure 1.21: Research Objectives on Decision Support System Aspect

1.8 Research Limitations

Through this research, several limitations are encountered. Thus, the research objectives are achieved subjected to these limitations:

1. Hardware limitation

- This research is conducted using a laptop computer running on Intel^R CoreTM i7-7500U CPU at 2.70–2.90 GHz with 20 GB RAM. Although the RAM is upgraded to a sufficient level and the processors are running on an adequate speed, the physical core of dual processors is limiting the numbers of Monte Carlo simulations performed in the rollout algorithm.
- Due to the core duo processors available, no parallel (parallel threading) Monte Carlo simulations could be performed that would potentially improve the computation time.
- Furthermore, the matheuristic rollout proposed are only limited to a certain numbers of nodes despite the reduced models proposed.
- Additionally, the number of vehicles performed by the matheuristic rollout is also limited in a certain test instance for benchmarking due to computing time that is no longer reasonable. Such case is deemed to be prohibitive as the computing time requires for the proposed base heuristics is clearly far superior.

2. Data limitation

- The test dataset that are simulated to emulate the scenario of 2015 Nepal earthquake in terms of the location and placement of the nodes in the road network. The real data during the event are difficult to obtained due to the sensitivity of the data.

1.9 Research Contributions

The contributions stemmed from this research could be viewed from four key aspects of the research as depicted in Figure 1.22.

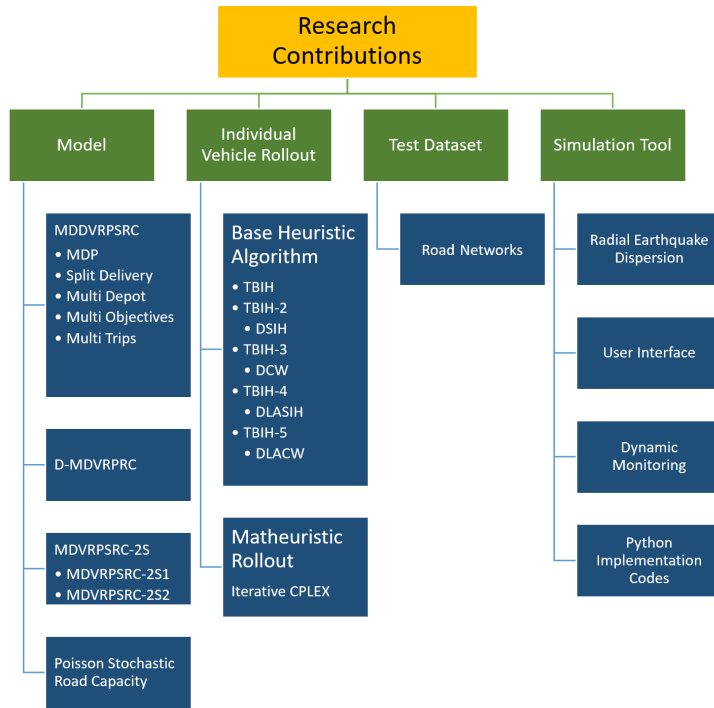

Figure 1.22: Research Contributions based on Research Components

From this research four models are developed and proposed prior to developing MD-DVRPSRC as a preliminary study:

1. D-MDVRPRC model for the case of deterministic road capacity.
2. Stochastic Integer Linear Programming (SILP) MDVRPSRC-2S model which derived further two reduced SILP models through which iterative decision rule is computed during rollout lookahead:
 - (a) MDVRPSRC-2S1 SILP model.
 - (b) MDVRPSRC-2S2 SILP model.
3. MDDVRPSRC MDP model.

Besides the MDVRPSRC-2S1 and MDVRPSRC-2S2 models, the D-MDVRPRC, MDVRPSRC-2S, and MDVRPSRC-2S incorporate a multi trip, multi objectives, multi depots, and split delivery operation.

Apart from these models, a radial dispersion earthquake lines is created to mimic the earthquake tremor that helps in determining road damages and the respective

deteriorating road capacity mean. Random road capacity is then sampled from road capacity distribution based on the Poisson distribution for each road in the network with the deteriorating road capacity mean as its parameter.

From the solutions of MDDVRPSRC perspective, few contributions are noted. First, the limitation of performing rollout with less Monte Carlo simulation is addressed by performing rollout for each vehicle individually instead of collectively as opposed to the conventional approach. Pivoting from this are the five presented base heuristics where TBIH-1 is first developed as the framework to differentiate the Teaching Part (TP) and the Seeking Part (SP) mechanism in determining a decision. Here SP consist of pure random selection of the next destination. Next, SIH (I1) is adopted in the SP mechanism forming TBIH-2 with embedded DSIH. The same is done by adopting CW forming TBIH-3 with embedded DCW. Deriving from these two each, are TBIH-4 with embedded DLASIH and TBIH-5 with embedded DLACW where the SP mechanism is improved by introducing lookahead in choosing promising nodes. Through these approaches it is shown how CW and SIH could be applied in the dynamic setting and could be modified further by introducing lookahead. To benchmark these proposed heuristic, new solution methodology is presented based on iterative CPLEX computation throughout every lookahead episode which can be coined as matheuristic rollout.

From the simulation tool perspective, a contribution is made by proposing a MD-DVRPSRC DSS platform consist of agent observing and computing the decision during the simulation, user interface, as well visualization showing the progression of the delivery operation simulation, all coded in Python 2.7. Through this DSS, the simulated data is compiled for comparative analysis.

1.10 Outline of Thesis

This thesis is organized beginning with Chapter 1 where the foundation of the research is elaborated including the research scope, research questions, problem statements, research objectives, research limitations, as well as the research contributions. Much can be discussed for the vast field of VRP and the respective solution algorithms. The author however, choose to focus instead on the concept of RL as this is the main theory that underpins the core of research. Chapter 2 elaborates on the literature review performed covering the narrowed down research scope discussed earlier in Chapter 1.

The methodology of the research in regards to conventional models, MDP models and the ADP solutions proposed as well as the MDDVRPSRC DSS are presented in Chapter 3, 4, 5 and 6 respectively.

Chapter 3 presents the deterministic and SILP models along with the road capacity distribution model based on the Poisson distribution. Here, the computation of the deteriorating road capacity mean based on the damage sustained by the road is also presented. In Chapter 4, the MDDVRPSRC model based on MDP with extended framework of Post Decision State (PDS) is presented while the solution methodology is introduced in Chapter 5. In this chapter, the matheuristic rollout as well as the TBIH-1 and its variants are introduced in a solution methodology based on ADP through the rollout implementation for each individual vehicle when needed. The MDDVRPSRC DSS is presented next in Chapter 6 detailing the Python classes, methods and threads as the building blocks of the DSS.

Meanwhile the computational results based on computational experiments performed in regards to models presented in Chapter 3 and Chapter 4 using the methodology described in Chapter 5 are presented in Chapter 7. Here, the development of test dataset is explained in detail. Furthermore, the analysis for respective computational experiments are also discussed in this Chapter. Finally, the research is summarized and concluded in Chapter 8.
