Abstract of thesis presented to the Senate of Universiti Putra Malaysia in fulfillment of the requirements for the degree of Doctor of Philosophy

PRECAST CONCRETE SANDWICH PANEL AS A BUILDING SYSTEM

By

BENAYOUNE ABDELGHANI

March 2003

Chairman: Professor Abang Abdullah Abang Ali

Faculty: Engineering

Precast Concrete Sandwich Panels (PCSP) that act as load bearing elements are structurally and thermally efficient building elements with potential for use as an Industrialised Building System (IBS).

The study aims to investigate all issues related to structural performance of PCSP. The strength characteristics of PCSP under imposed loads with both wythes being structural wythes were established and the condition for achieving composite behaviour was examined. Although it is possible to use any conventional flooring system with the use of PCSP as walling elements, the structural behaviour of PCSP under lateral load was also studied so that PCSP can be adopted as flooring elements. This helps to reduce the number of different types of elements necessary in a building. A study on typical connections between PCSP elements was also undertaken.

Under axial and eccentric loads, an experimental program consisting of twelve specimens with different heights was carried out. The theoretical investigation consists of two theoretical formulations namely, classical expressions and Finite

Element Method (FEM). Comparison between non-linear FEM proposed models and experimental data was made in order to validate the models.

An FEM parametric study was carried out by varying two important parameters i.e. the effect of slenderness (height-to-thickness ratio, H/t) and the stiffness of the shear connectors as measured by the bar diameter. The ultimate strength of the PCSP was found comparable to the strength expected for full composite panels. It achieved a high composite behaviour at service and acted in partially composite manner at ultimate stage. A study on the effect of opening in the form of doors and windows in the sandwich panels was also undertaken. It was found that the ultimate load of the PCSP decreases with increase in slenderness ratio (H/t). Simplified design formulae to determine the ultimate strength of PCSP under axial and eccentric loads were proposed to closely match the strength values.

The FEM investigation was extended to explore the feasibility of usage of PCSP as slab. Two non-linear FEM models (2-D and 3-D models) were used to simulate the behaviour of PCSP as one-way and two-way acting slabs respectively. The non-linear FEM models were validated by experimental data. Parameters such as shear connector numbers and applied loading influencing the ultimate strength and the compositeness of the PCSP working as slab were investigated. A method for the determination of the interface shear force and the design of shear connectors was proposed. The results as obtained experimentally indicated that the classical elastic theory assuming fully composite action and non-linear FEM models were reasonably accurate in predicting ultimate loads and lateral deflections.

The behaviour of typical vertical connections between two precast concrete sandwich panels under shear and bending using FEM was carried out. FEM results were found to be in good correlation with experimental values. Ultimate strength,

ductility of the connection, strain in anchor steel bars, strains variations across the critical zone together with cracking patterns and mode of failure were studied. The proposed FEM model predicted with an acceptable accuracy the general behaviour of the connections under moment and shear forces. On the basis of this investigation, connection reinforcement details were recommended.

Abstrak tesis yang dikemukakan kepada Senat Universiti Putra Malaysia

**PANEL SANDWIC KONKRIT PASANG DAHULU SEBAGAI
SISTEM BINAAN**

Oleh

Mac 2003

Pengerusi: Profesor Abang Abdullah Abang Ali

Fakulti: Kejuruteraan

Panel Dinding Sandwic Konkrit Pasang Dahulu (PCSP) gelas beban adalah elemen yang mempunyai ciri-ciri struktur yang kukuh dan penebat haba yang berkesan. Panel PCSP juga berpotensi untuk di jadikan sebagai salah satu Sistem Binaan Industri (IBS) yang ekonomi.

Objective utama penyelidikan ini adalah bertujuan untuk mewujudkan panel sandwic gelas beban yang berpotensi sebagai salah sebuah sistem binaan yang terunggul. Penyelidikan bertujuan untuk mengenalpasti segala isu yang berkaitan dengan sifat-sifat kejuruteraan struktur PCSP. Dengan itu, ciri-ciri kekuatan PCSP akibat beban kenaan terhadap dinding tersebut dapat di kenalpasti dan sifat rencam dinding sandwic panel dapat di selidiki dengan lanjut. Untuk mengurangkan bilangan elemen yang di perlukan dalam sistem binaan tersebut, panel PCSP juga telah di uji sebagai sistem papak. Dengan itu, ujian terhadap panel PCSP dengan di kenakan beban sisi telah di jalankan. Penyelidikan terhadap sistem sambungan antara elemen-elemen PCSP juga telah di kaji.

Program ujikaji terhadap dua belas panel yang di kenakan beban paksi dan beban siji serta ketinggian panel yang berbeza di jalan kan. Sifat kelangsingan dan kesipian beban terhadap kekuatan panel telah di kaji. Kajian melalui teori secara lazim dan secara kaedah unsur terhingga (FEM) telah di laksanakan. Untuk mengesahkan model tak lurus FEM yang di cadangkan, perbandingan antara data-data ujikaji telah di lakukan.

Kajian berparameter melalui FEM telah di jalankan dengan mengubahsuai dua parameter penting iaitu kesan kelangsingan (nisbah tinggi ke tebal, H/t) dan kekuhan penyambung ricihan melalui perubahan garispusat bar. Melalui kajian ini, di dapati bahawa kekuatan muktamad PCSP mempunyai nilai yang menghampiri kepada panel yang bercirikan rencam penuh. Kajian terhadap panel dengan pembukaan seperti tingkap dan pintu juga telah di jalankan. Dalam kajian itu, di dapati bahawa kekuatan muktamad panel menurun dengan bertambahnya nisbah kelangsingan (H/t). Dari itu, persamaan rekabentuk dapat dihasilkan untuk memberikan nilai kekuatan muktamad PCSP akibat beban paksi dan beban siji.

Kajian FEM telah di perluaskan terhadap PCSP sebagai sistem papak. Dua FEM model tak lurus (model 2-D dan 3-D) telah di cadangkan untuk mengkaji sifat-sifat papak satu-hala dan dua hala. Model FEM tak lurus tersebut telah di perbandingkan dan di sahkan dengan data-data ujikaji. Parameter seperti bilangan penyambung ricihan dan beban keaanan yang mempengaruhi kekuatan muktamad dan kerencaman PCSP sebagai papak telah di kaji. Satu kaedah untuk menentukan daya ricih di antara muka papak dan rekabentuk penyambung ricihan telah dapat di cadangkan. Keputusan kajian menunjukkan bahawa teori kenyal secara lazim dan model FEM tak lurus adalah memuaskan dalam meramal beban muktamad dan pesongan sisi.

Kajian terhadap sambungan menegak antara dua panel sandwic konkrit pasang dahulu terhadap daya ricih dan momen lentur telah di jalankan dengan menggunakan model FEM. Keputusan model FEM menunjukkan nilai yang setanding dengan ujikaji. Kekuatan muktamad, kemuluran sambungan, keterikan pada bar pengikat, perubahan keterikan pada zon kritikal serta corak retakan dan ragam kegagalan telah di bentangkan. Model FEM yang dicadangkan telah memberi ramalan keputusan yang memuaskan terhadap sambungan yang di kenakan daya ricih dan momen lentur. Hasil dari kajian ini, tetulang untuk sambungan tersebut dapat di syorkan.

ACKNOWLEDGEMENTS

I would like to express my sincere gratitude to Prof. Dr. D.N. Trikha and Prof. Ir. Abang Abdullah Abang Ali for their invaluable guidance and patience throughout the research program. I also wish to extend my appreciation to Assoc. Prof. Dr. Ir. Abdul Aziz Abdul Samad & Prof. Dr. Anvar A. Ashrakov for their kind help, support and constructive comments.

I also appreciate the assistance of the technical staff of Structural Engineering Laboratory especially that of Hj. Ghazali Said, Mr. Baharuddin Abdul Karim and Mr. Mohd Halim Osman. The support of the IRPA Research Grant is gratefully acknowledged .

My parents were always supporting and encouraging me throughout my years in college. I cannot thank them enough for devoting their lives to their children's education. Dedicating this dissertation to them is the least I can do to show my appreciation. I would like also to thank all my sisters and brothers not only for their support and encouragement, but also for being the best sisters and brothers anybody can have. Likewise, I would like to thank my wife Sofia, for her love, encouragement and patience.

Many thanks to all the friends I met during my stay in UPM for making this place a second home away from home. Finally, I thank Allah for HE always direct my path and always answer my prayers.

A. Benayoune

5.18	Ultimate strength versus slenderness	201
5.19	Load-deflection profile – Analysis III	204
5.20	Buckling load versus slenderness ratio (H/t)	204
5.21	Buckling load to ultimate load ratio versus slenderness ratio	205
5.22	Load-deflection profile – Analysis III	206
5.23	Comparison between buckling and crushing failure for panel PE8	206
5.24	Comparison between axial and eccentric Buckling Analysis III	207
5.25	Buckling modes of PCSP - Analysis I	208
5.26	Mode of failure against shear connector bar diameter under axial load Analysis I & II	209
5.27	Slenderness against buckling load – Analysis II	210
5.28	Comparison of design axial strengths	212
5.29	Slenderness functions versus slenderness ratio	213
5.30	Displacement contour for the panel PN	217

5.31	Compressive stress contour for the panel PN	217
5.32	Displacement contour for the panels PD and PN	219
5.33	Displacement variations at section A-A for the panels PD and PN	219
5.34	Compression stress contour for the panel PD	220
5.35	Compressive stress variations at section A-A for the panels PD and PN	220
5.36	Tensile stress contour for the panels PD	221
5.37	Tensile stress variations at section A-A for the panels PD and PN	221
5.38	Stress variation across the beam strip (A2-A2) from top to bottom	222
5.39	Stress variation across the section A1-A1 at mid-height of PD	222
5.40	Deformed shape and displacement contour for the panel PW	224
5.41	Displacement variation at section B-B for the panel PW and PN	224
5.42	Principal compressive stress contour for the panels PW	225
5.43	Principal compressive stress variation at section B-B for the panels PW and PN	225
5.44	Principal tensile stress contour for the panel PW	226
5.45	Tensile stress variation at section B-B for the panels PW and PN	226
5.46	Stress variation at the section B2-B2 for panel PW	227
5.47	Stress variation the section B1-B1 at mid-height of PW	227
5.48	Deformed shape and displacement contour for the panel PDW	229
5.49	Displacement variation at section C-C for the panel PDW and PN	229
5.50	Principal compressive stress contour for the panels PDW	230
5.51	Principal compressive stress variation at section C-C for the panels PDW and PN	230
5.52	Principal tensile stress contour for the panel PDW	231
5.53	Tensile stress variation at section C-C for the panels PDW and PN	231
5.54	Stress variation at section C2-C2 for the panel PDW	232
