

Occurrence of thermophilic *Campylobacter* spp. contamination on vegetable farms in Malaysia.

ABSTRACT

The aim of the present study was to examine the prevalence of thermophilic *Campylobacter* spp. (*Campylobacter jejuni* and *Campylobacter coli*) in soil, poultry manure, irrigation water, and freshly harvested vegetables from vegetable farms in Malaysia. *C. jejuni* was detected in 30.4% and 2.7% of the soil samples, 57.1% and 0% of the manure samples, and 18.8% and 3% of the vegetable samples from farm A and farm B, respectively, when using the MPNPCR method. *Campylobacter* spp. was not found in any of the irrigation water samples tested. Therefore, the present results indicate that the aged manure used by farm A was more contaminated than the composted manure used by farm B. Mostly, the leafy and root vegetables were contaminated. *C. coli* was not detected in any of the samples tested in the current study. Both farms tested in this study were found to be contaminated by campylobacters, thereby posing a potential risk for raw vegetable consumption in Malaysia. The present results also provide baseline data on *Campylobacter* contamination at the farm level.
