

Optical response of WO₃ nanostructured thin films sputtered on different transparent substrates towards hydrogen of low concentration.

Abstract

The gasochromic response of WO₃ nanostructured films coated with a catalytic Pt or Pd layer on different transparent substrates upon exposure to H₂ gas was investigated. WO₃ nanostructured films with 500 nm thickness were coated with a 25 Å thick Pt or Pd layer. The films were prepared on quartz, glass, indium-doped tin oxide (ITO) and fluorine-doped tin oxide (FTO) conductive glass. The nanostructured WO₃ was deposited by RF magnetron sputtering, and the Pt or Pd layer was deposited by DC sputtering. Characterization of the film revealed that the WO₃ was deposited as nanoscale grains of varied size depending on the substrate. WO₃ grains on quartz and glass were 30–40 nm in size. WO₃ grain sizes on ITO and FTO were 40–60 nm and 300–500 nm, respectively. The WO₃ films were observed to show strong gasochromic response, with absorbance changes measured in the Vis-NIR (500–1100 nm) range. The cumulative absorbance response towards H₂ is the highest and more stable for Pd/WO₃ films on quartz, glass and ITO, compared to the FTO substrate. The gasochromic effect was also stronger in Pd/WO₃ films compared to Pt/WO₃ films.
