Transformation

Male

Female

Insects, like human being, they grow. Insects undergo a series of transformations in their life that includes changes in forms, textures and physical appearances which is called metamorphosis. The journey to adulthood begins with females producing eggs which will then hatch becoming the immature stage. The insect's immature stage undergoes a series of changes in size called instars where they will shed their skins a couple of time before becoming an adult. Insect with incomplete metamorphosis undergoes three different life stages. The eggs will develop into nymph which is a miniature version of the adult form but lacking of wings and genitalia. True bug, dragonfly, cicada and cockroach are example of insect that undergo this process. In reflection to human's life, we aim to change for the betterment either physically or most importantly, spiritually. The process of 'shedding' our old bad habits gradually is like the journey to become a better person and at the end reach full maturity in the way of thinking and action.
