

## RTS noise reduction of CMOS image sensors using amplifier-selection pixels

### ABSTRACT

This paper describes a RTS (random telegraph signal) noise reduction technique for an active pixel CMOS image sensor (CIS) with in-pixel selectable dual source-follower amplifiers. In this CMOS image sensor, the lower-noise transistor in each pixel is selected in the readout operation using a table of determining the lower-noise transistors of all the pixels. A prototype image sensor with  $65 \times 290$  pixels for demonstrating the effectiveness of this technique has been implemented using  $0.18\mu\text{m}$  CMOS image sensor technology with pinned photodiode option. The measured result shows that the maximum noise using the amplifier-selection technique is reduced to  $9.6\text{e-}$  from  $17.2\text{e-}$  which is the maximum noise of the image array using one of two amplifiers in each pixel without selection.
