Abstract of thesis presented to the Senate of Universiti Putra Malaysia in fulfilment of the requirement for the degree of Master of Science.

**MICROWAVE EXTRACTION OF ESSENTIAL OILS FROM *JASMINUM*
SAMBAC FLOWERS**

By

NURSHAHIDAH BINTI OSMAN

November 2006

Chairman: Professor Kaida bin Khalid, PhD

Faculty: Science

The Microwave Extraction System (MES) is a high-speed method used to extract target compounds from various raw materials. It was originally developed for the extraction of flavors and fragrances from plant materials, which is generally carried out by conventional techniques that require a lot of energy or a long time or a combination of both. In this study, a microwave extraction system (MES) is developed for the extraction of essential oils from *Jasminum sambac* flowers. The important MES process parameters, i.e, time, temperature and microwave power are controlled to obtain rapidly the highest quantity and quality of oil. The performance of MES is compared with the Conventional Extraction Method (CEM) using various methods such as dry distillation (DD), wet distillation (WD), hydro distillation (HD) and steam distillation (SD) in terms of rapidity, quality and percentage of yield, chemical composition of oil and its efficiency. The MES is performed by DD and WD at irradiation power of about 450 W and temperature about 100 °C for 1 hour whereas CEM is performed by HD and SD at

extraction power of 450 W and temperature 100 °C for 8 hours. The absorption power of microwave irradiation by *Jasminum sambac* flowers are predicted for DD and WD. The project has successfully proved that MES is more efficient than CEM in terms of rapidity, quality and quantity of yield, energy use, easiness in operation and cost effectiveness. The MES provides a rapid extraction, with about 8 times faster than CEM. After 1 hour of microwave extraction, it is possible to collect sufficient essential oil which provides comparable yields to those obtained with 8 hours by CEM. Using MES, DD requires only 5 minutes to obtain its first oil droplet and WD requires 8 minutes whereas using CEM, both HD and SD allows 15 and 42 minutes respectively to obtain the first oil droplet. DD requires less time to obtain its first oil droplet compared to other methods because the absorption power for dry sample is higher than for wet sample. The DD technically gives higher percentage yield with 0.10 % which is about 5 times higher compared to SD and HD where both only contribute 0.02 %, respectively whereas WD contributes 0.06 %. Although more compounds are detected in the essential oil extracted by CEM, substantial higher amounts of highly odoriferous compounds are present in the MES extract. The relative amount of oxygenated fraction in essential oil is less than 30 % for CEM and more than 30 % for MES. In terms of the energy consumed, the energy consumption in MES is 8 times lower than in CEM. HD requires heating of 0.4 liter of water and 200 g of flowers to the extraction temperature, and evaporating the water and essential oil for 8 hours whereas DD only requires heating 200 g of fresh flowers and evaporating the in situ water and essential oil of the plant material for 1 hour. Furthermore, MES requires maximum power irradiation only to heat up the sample and water to its boiling point and thus obtain its first oil droplet whereas CEM requires maximum power irradiation throughout the process. Essentially, the MES provides an

easily controlled system, rapid extraction process; high yield and purity extracts, more valuable essential oils, extracts with chemical compositions comparable to conventional method and allows a substantial saving of energy. These advantages not only reduce operating costs, but also result in a more environmentally friendly process.

Abstrak tesis yang dikemukakan kepada Senat Universiti Putra Malaysia sebagai memenuhi keperluan untuk ijazah Master Sains

**PENGEKSTRAKAN GELOMBANG MIKRO BAGI MINYAK PATI DARIPADA
BUNGA *JASMINUM SAMBAC***

Oleh

NURSHAHIDAH BINTI OSMAN

November 2006

Pengerusi: Profesor Kaida bin Khalid, PhD

Fakulti: Sains

Sistem Pengekstrakan Gelombang Mikro ataupun dikenali dengan *Microwave Extraction System* (MES) merupakan suatu kaedah berkelajuan tinggi yang digunakan untuk mengekstrak komposisi-komposisi sasaran daripada pelbagai bahan mentah. Sistem ini pada asalnya dimajukan untuk pengekstrakan bahan-bahan perisa dan pewangi daripada tumbuh-tumbuhan yang kebiasaannya dijalankan oleh kaedah-kaedah konvensional yang memerlukan penggunaan tenaga yang banyak atau masa pengekstrakan yang terlampau lama atau kedua-duanya sekali. Dalam kajian ini, sebuah sistem pengekstrakan gelombang mikro (MES) dibina untuk pengekstrakan minyak pati dari sampel bunga *Jasminum sambac*. Parameter-paramater proses MES yang penting seperti masa, suhu dan kuasa gelombang mikro dikawal untuk mencapai ekstrak minyak pati yang paling maksimum dan berkualiti tinggi dalam masa yang singkat. Prestasi MES dibandingkan dengan Teknik Pengekstrakan Biasa ataupun dikenali sebagai *Conventional Extraction Method* (CEM) menggunakan pelbagai kaedah seperti penyulingan kering (DD), penyulingan basah (WD), penyulingan hidro (HD) dan

penyulingan wap (SD) dari segi kepantasan, kualiti dan peratusan minyak, komposisi kimia minyak dan kecekapannya. MES dilakukan secara DD dan WD yang dijalankan pada kuasa sinaran 450 W dan suhu di sekitar 100 °C selama 1 jam manakala CEM dilakukan secara HD dan SD yang dijalankan pada kuasa pengekstrakan 450 W dan suhu 100 °C selama 8 jam. Kuasa serapan sinaran gelombang mikro oleh bunga *Jasminum sambac* diramal bagi DD dan WD. Projek ini telah membuktikan dengan jayanya bahawa MES lebih efisien berbanding CEM dari segi kepantasan, kualiti dan kuantiti minyak yang terhasil, penggunaan tenaga, kemudahan pengoperasian dan penjimatan kos. MES memberikan pengekstrakan yang cepat, lebih kurang 8 kali lebih pantas dari CEM. Selepas 1 jam pengekstrakan menggunakan gelombang mikro, adalah mungkin untuk mengumpul semua minyak pati yang mencukupi bagi tujuan penyelidikan dan memberikan hasil ekstrak yang setara dengan 8 jam pengekstrakan menggunakan CEM. Didapati titisan minyak pertama yang jatuh dikesan antara minit kelima bagi DD dan minit kelapan bagi WD sementara HD dan SD masing-masing memerlukan 15 dan 42 minit untuk mencapai titisan minyak pati pertama. DD mengambil masa yang lebih singkat untuk mendapatkan titisan minyak pertama berbanding kaedah-kaedah lain kerana kuasa serapan bagi sampel kering lebih tinggi daripada kuasa serapan bagi sampel basah. Secara teknikal, DD menyumbangkan peratusan ekstrak minyak yang lebih tinggi iaitu sebanyak 0.1 % iaitu 5 kali ganda berbanding kaedah-kaedah CEM yang lain iaitu HD dan SD yang hanya menyumbangkan minyak sebanyak 0.02 % masing-masing manakala WD memberikan hasil sebanyak 0.06 %. Walaupun jumlah sebatian dikesan lebih banyak dalam ekstrak CEM, namun didapati lebih banyak sebatian pewangi yang wujud dalam ekstrak MES. Secara relatifnya, peratusan sebatian wangi di dalam minyak CEM adalah kurang dari 30

% sementara peratusan sebatian wangi di dalam minyak CEM adalah lebih dari 30 %. Dari segi penggunaan tenaga, MES menggunakan tenaga sebanyak 8 kali lebih rendah berbanding CEM. HD memerlukan pemanasan 0.4 liter air dan 200 g sampel bunga untuk mencapai suhu pengekstrakan 100 °C dan mengewap minyak pati di dalam sampel serta tambahan air yang dibuat selama 8 jam manakala DD hanya memerlukan pemanasan 200 g sampel bunga dan mengewap kandungan minyak pati dan air di dalam sampel selama 1 jam. Tambahan pula, MES memerlukan penggunaan sinaran kuasa maksimum hanya untuk memanaskan sampel dan air ke takat didihnya dan seterusnya mencapai titisan minyak pertama manakala CEM memerlukan sinaran kuasa maksimum sepanjang proses berjalan. Paling utama, MES merupakan suatu sistem kawalan yang amat mudah, proses pengekstrakan yang pantas, menghasilkan minyak yang lebih banyak, tulen serta berkualiti tinggi, memberikan komposisi minyak pati yang setara dengan CEM serta membenarkan penjimatan tenaga yang banyak. Kelebihan-kelebihan ini bukan sahaja menjimatkan kos malah menyumbangkan kepada suatu proses yang mesra alam.

ACKNOWLEDGEMENTS

Many people contributed to the creation of this book but first and foremost, I thank Allah S.W.T for the health, ability and resources that have sustained me in this life.

I would like to express my deep appreciation to my supervisor who is also the chair of the supervisory committee, Professor Dr. Haji Kaida bin Khalid for his invaluable thoughts, attentive suggestions and unlimited support throughout my master program. His breadth of knowledge guided my research on several occasions. Also, I would like to express a great appreciation and special thanks to my co-supervisors, Associate Professor Dr. Haji Aspollah Haji Md. Sukari and Dr. Jumiah Hassan for their support, guidance and knowledge throughout the study.

Among others I would particularly like to thank are Encik Roslim, Encik Zul, Encik Zainal, Encik Ishar, Encik Radzi and my colleagues for their various encouragement or practical help in other ways. I also owe gratitude in particular to my labmate, Encik Rudy bin Nurdin for his invaluable help and co-operation in sharing ideas and information concerning my dissertation and others who had helped me throughout this project. Last but not least, I would like to thank my family especially my parents, Osman bin Bakar and Badariah binti Ahmad for their love and support to me, their sacrifices and understanding from the very beginning of my work until my master studies were completed. May Allah reward them all the best of rewards in the Hereafter.

I certify that an Examination Committee has met on 17th November 2006 to conduct the final examination of Nurshahidah binti Osman on her Master of Science thesis entitled “Microwave Extraction of Essential Oils from *Jasminum sambac* Flowers” in accordance with Universiti Pertanian Malaysia (Higher Degree) Act 1980 and Universiti Pertanian Malaysia (Higher Degree) Regulations 1981. The Committee recommends that the candidate be awarded the relevant degree. Members of the examination Committee are as follows:

Wan Mohamad Daud Wan Yusoff PhD

Associate Professor
Faculty of Science
Universiti Putra Malaysia
(Chairman)

Azmi Zakaria, PhD

Associate Professor
Faculty of Science
Universiti Putra Malaysia
(Internal Examiner)

Zulkifly Abas, PhD

Associate Professor

CHAPTER 1

INTRODUCTION & LITERATURE REVIEW

1.1 Introduction

The initial surge in microwave technology development was driven by the military needs of the Second World War. The tremendous effort that went into development of radar during Second World War generated a great body of knowledge on the properties of microwaves and related technologies [1]. After the Second World War, a rapid growth of microwaves system has taken place in the area of telecommunication and navigation in both civilian and military. However, industrial, scientific, medical and domestic applications have developed at a slower pace. Most microwave applications fall in the range 300 MHz to 300 GHz [2].

By far, the most popular application of microwave power is in microwave oven for domestic and commercial cooking, heating and drying. Household and institutional microwave ovens operate at the frequency of 2450 MHz and the lower microwave frequency 915 MHz is currently only used for industrial applications. On the other hand, a greater variety of industrial applications of high microwave power has been demonstrated including applications in various industries such as rubber, food, textiles, plastics, foundry, building materials, paper, pharmaceuticals, cosmetics, and coal. The main advantages of microwave power in processing of materials are increased rate of
