Faculty: Science

Vanadium phosphate catalyst is well known for the selective oxidation of *n*-butane to maleic anhydride process. In this study, the behavior of oxygen species in vanadium phosphate catalysts was investigated using temperature programmed analyses. Besides, the effects of Mo and Te dopants addition and mechanochemical treatment also have been studied. A new method to synthesis $\text{VOPO}_4 \cdot 2\text{H}_2\text{O}$ using milling technique (mechanosynthesis) also included in the study. The catalysts were synthesized by calcining the precursor, $\text{VOHPO}_4 \cdot 0.5\text{H}_2\text{O}$ in a flow of *n*-butane in air (0.75% *n*-butane in air) for 16 h at 733 K. Precursor was obtained by reduction of $\text{VOPO}_4 \cdot 2\text{H}_2\text{O}$ using *iso*-butyl alcohol. The physico-chemical properties of the catalysts were characterized by using x-ray diffraction (XRD), BET surface area measurement, redox titration, inductively coupled plasma-atomic emission spectroscopy (ICP-AES), scanning electron microscopy (SEM) and temperature programmed analyses. The catalytic properties of the selected catalysts were carried out by using temperature programmed reaction (TPRn) and on-line microreactor system. A comparison between the fresh and used catalysts in aerobic and anaerobic condition gave the better understanding about the lattice oxygen species which took

part in the selective oxidation. It was found that, certain amount of O^{2-} species which associated with V^{5+} plays an important role in selectivity for maleic anhydride because no O^{2-} species was detected by temperature programmed reduction (H_2 -TPR) for the used catalyst in anaerobic condition. This result also supported by TPRn profile for the post O_2 -desorbed catalyst where the catalyst with only O^- species gave no significant selectivity compared to catalyst with both oxygen species (O^{2-} and O^-). However, deleterious effect was observed for catalysts with high number of V^{5+} species (catalysts from mechanochemically treated doped precursors). High amount of O^{2-} species was obtained by H_2 -TPR for these catalysts. However, this oxygen species only promotes total oxidation as only CO_2 was observed in *n*-butane oxidation. Introduction of Mo and Te into the catalyst precursor did not change the phase of the final catalysts. However the doped catalysts consist only platelets particles and no rosette clusters morphology as usually observed for dihydrate route catalyst. Mechanochemical treatment on the doped precursors did not change the $VOHPO_4 \cdot 0.5H_2O$ phase of the precursors but increased the number of β - $VOPO_4$ in the catalysts stage. Besides that, the surface area reduced significantly and the morphology also changed from platelets to blocky shape. According to the TPRn results, all the catalysts from the doped precursor gave higher conversion compared to undoped counterpart. However, the catalysts from mechanichemically treated doped precursors have low selectivity because no intermediate products were observed. A new method of $VOPO_4 \cdot 2H_2O$ preparation was successfully carried out using mechanosynthesis method. The product synthesized ($VOPO_4 \cdot 2H_2O$) in 2 h at 1400 rpm using agate materials has lower crystallinity compared to the refluxed counterpart. The surface area for the catalyst produced from the mechanosynthesized $VOPO_4 \cdot 2H_2O$ was slightly lower than conventional catalyst but increased after the

precursor was mechanochemically treated prior calcination step. Meanwhile, the total oxygen removed for the catalysts from mechanosynthesized $\text{VOPO}_4 \cdot 2\text{H}_2\text{O}$ was lower compared to conventional catalyst.

Abstrak tesis yang dikemukakan kepada Senat Universiti Putra Malaysia sebagai memenuhi keperluan untuk ijazah Doktor Falsafah

**SIFAT-SIFAT FIZIKAL-KIMIA DAN KELAKUAN SPESIS OXIGEN
DALAM PEMANGKIN VANADIUM FOSFAT GUMPALAN DAN
DIMODIFIKASI UNTUK PENGOKSIDAAN SEPARA *N*-BUTANE**

Oleh

Fakulti: Sains

Mangkin vanadium fosfat terkenal dengan process pengoksidaan terpilih *n*-butana kepada maleik anhidrida. Dalam kajian ini, sifat-sifat spesies oksigen dalam mangkin vanadium fosfat telah dikaji menggunakan analisis suhu terprogram. Selain itu, kesan-kesan daripada dopan Mo dan Te serta rawatan mekanokimia turut dikaji. Kaedah baru dalam sintesis $\text{VOPO}_4 \cdot 2\text{H}_2\text{O}$ dengan menggunakan teknik kisanan (mekanosintesis) juga disertakan dalam kajian ini. Mangkin-mangkin telah disintesis dengan mengkalsinkan prekursor, $\text{VOHPO}_4 \cdot 0.5\text{H}_2\text{O}$ dalam aliran *n*-butana dalam udara (0.75 % *n*-butana dalam udara) selama 16 j pada 733 K. Prekursor disintesis dengan menurunkan $\text{VOPO}_4 \cdot 2\text{H}_2\text{O}$ menggunakan alkohol *iso*-butil. Sifat-sifat fizikal-kimia mangkin telah dicirikan dengan menggunakan pembelauan sinar-X (XRD), pengukuran luas permukaan BET, pentitratan redox, plasma gandingan teraruh-spektoskopi pancaran atom (ICP-AES), mikroskopi electron imbasan (SEM) dan analysis-analysis suhu terprogram. Sifat pemangkinan untuk mangkin terpilih telah dijalankan dengan menggunakan reaksi suhu terprogram (TPR_n) dan sistem rektor mikro on-line. Perbandingan di antara mangkin segar dan mangkin terpakai dalam keadaan aerobik dan anaerobik memberikan pemahaman yang lebih baik berkenaan

spesis oksigen kekisi yang memainkan peranan dalam pengoksidaan terpilih. Didapati bahawa sejumlah spesies O^{2-} yang dikaitkan dengan V^{5+} memainkan peranan penting dalam selektiviti kepada maleik anhidrida kerana tiada spesies O^{2-} dikesan oleh penurunan suhu terprogram (H_2 -TPR) untuk mangkin terpakai dalam keadaan anaerobik. Keputusan ini disokong oleh profil TPRn untuk mangkin selepas penyahjerapan- O_2 di mana mangkin yang mempunyai spesies O^- memberikan selektiviti yang tidak signifikan berbanding dengan mangkin yang mempunyai kedua-dua spesies oksigen (O^{2-} and O^-). Walaubagaimanapun, kesan buruk telah diperhatikan untuk mangkin dengan jumlah spesies V^{5+} yang tinggi (mangkin dari prekursor didop yang dirawat secara mekanokimia). Namun spesies O^{2-} yang tinggi didapati oleh H_2 -TPR untuk mangkin-mangkin tersebut. Walaubagaimanapun, spesies oksigen ini mempromosikan pengoksidaan lengkap di mana hanya CO_2 diperhatikan dalam pengoksidaan *n*-butana. Pengenalan Mo dan Te ke dalam prekursor mangkin tidak mengubah fasa pada mangkin. Walaubagaimanapun, mangkin-mangkin yang didop hanya mengandungi partikel kepingan dan tiada morfologi kluster ros yang selalu diperhatikan untuk mangkin dari laluan dihidrat. Rawatan mekanokimia pada prekursor yang didop tidak mengubah fasa $VOHPO_4 \cdot 2H_2O$ prekursor tetapi menambahkan bilangan β - $VOPO_4$ dalam peringkat mangkin. Selain itu, luas permukaan berkurangan secara signifikan dan morfologi juga berubah dari kepingan ke bentuk blok. Menurut keputusan TPRn, semua mangkin dari prekursor didop mempunyai penukaran yang lebih tinggi berbanding mangkin yang tidak didop. Walaubagaimanapun, mangkin-mangkin dari prekursor didop dirawat secara mekanokimia mempunyai selektiviti yang rendah kerana tiada produk pertengahan yang dikesan. Kaedah baru penghasilan $VOPO_4 \cdot 2H_2O$ telah berjaya dilaksanakan dengan menggunakan kaedah mekanosintesis. Produk ($VOPO_4 \cdot 2H_2O$) disintesis

dalam 2 j pada 1400 ppm menggunakan bahan agate mempunyai tahap kristal yang rendah berbanding yang direfluks. Luas permukaan mangkin dari $\text{VOPO}_4 \cdot 2\text{H}_2\text{O}$ mekanosistesis kurang sedikit berbanding mangkin konvensional tetapi meningkat selepas prekursor dirawat secara mekanokimia sebelum langkah pengkalsinan. Semetara itu, jumlah oksigen yang dikeluarkan dari mangkin dari $\text{VOPO}_4 \cdot 2\text{H}_2\text{O}$ mekanosintesis lebih rendah berbanding mangkin konvensional.

ACKNOWLEDGEMENTS

I wish to express my sincere appreciation for my supervisor, Professor Dr. Taufiq Yap Yun Hin for his guidance, patience and invaluable discussion throughout the course of this work. The gratitude also extended to co-supervisors, Professor Dr. Mohd Zobir Hussein and Professor Dr. Zulkarnain Zainal for their supervision.

I also wish to thank Madam Choo Chai Syam, Puan Zaidina Md. Daud and other Science Officers in the Department of Chemistry, Faculty of Science for their assistance in the characterization works. Not to forget officers in Microscopy Unit, Institute Bioscience especially Puan Faridah and Mr. Ho for their help and advice in running SEM.

I am also very grateful to Mr. Theam Kok Leong, Dr. Ali Asghar Rownaghi, Mr. Wong Yee Ching, Mr. Yuen Choon Seon, Miss Woi Pei Meng, Miss Nor Asrina Sairi, Miss Siti Murni Zawawi, colleagues and friends for their help, support and discussion during my stay in the PutraCat Laboratory, Universiti Putra Malaysia.

Most especially, I wish to thank my family for their love, never ending support and encouragement for these years.

Financial support from the Ministry of Science, Technology and Innovative of Malaysia (MOSTI) is gratefully acknowledged.

I certify that an Examination Committee has met on 15th August 2008 to conduct the final examination of Tang Wen Jiunn on his Doctor of Philosophy thesis entitled “Physico-Chemical Properties and Oxygen Species Behavior Of Bulk and Modified Vanadium Phosphate Catalyst for Partial Oxidation Of *n*-Butane” in accordance with Universiti Pertanian Malaysia (Higher Degree) Act 1980 and Universiti Pertanian Malaysia (Higher Degree) Regulations 1981. The Committee recommends that the student be awarded the degree of Doctor of Philosophy.

Members of the Examination Committee were as follows:

Mohd Aspollah Sukari, PhD

Professor
Faculty of Science
Universiti Putra Malaysia
(Chairman)

Anuar Kassim, PhD

Professor
Faculty of Science
Universiti Putra Malaysia
(Internal Examiner)

Tan Yin Ping, PhD

CHAPTER 1

INTRODUCTION

1.1 Catalysis in General

In general, catalyst is a substance that increases the rate of a reaction (Atkins and Paula, 2002). It happens by introducing new pathways with lower Gibbs activation energy, ΔG as shown in Figure 1.1. Although the activation energy is much lower than the uncatalyzed reaction, the Gibbs energy of overall reaction, ΔG^\ominus remain the same (Shriver and Atkins, 2001). It is important that the product is released in a thermodynamically favorable step.

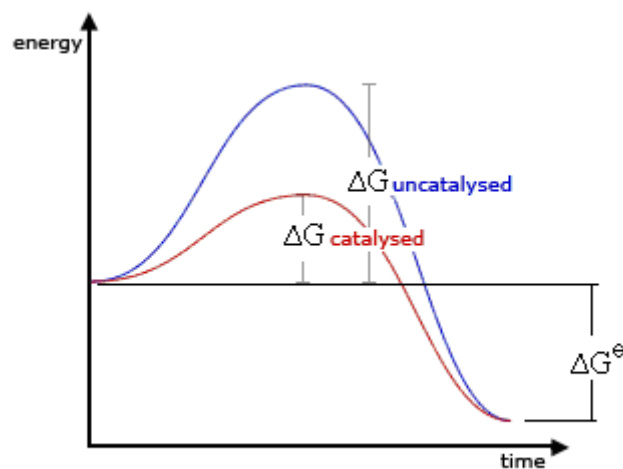

Figure 1.1. Schematic representation of the activation energy between catalyzed and uncatalyzed reaction (Shriver and Atkins, 2001)

A good catalyst should have three important criteria (Shriver and Atkins, 2001 and Atkins and Paula, 2002):

i) Activity

An active catalyst should have a strong chemisorption ability in order to attract reactant. However if it is too strong, the activity declines either because other reactants cannot react with the adsorbate or because the adsorbate molecules block the active sites thus prevent further reaction.

ii) Selectivity

A selective catalyst should produce high percentage of desired product with minimum amount of side products. It is economically important because highly selective catalysts reduce the consumption of reactants thus reduce the operation cost.

iii) Life time

A catalyst must survive through a large number of cycles. However, side reactions or presence of impurities in the reactants might deactivate the catalyst.

1.2 Selective Heterogeneous Oxidation Catalysis

Selective heterogeneous oxidation catalysis is playing an important role to the well-being of society since it produces about 25% of the most important industrial organic chemicals and intermediates such as acrolein, maleic anhydride, ethylene and phthalic anhydride to be used in the manufacture of industrial products and consumer

goods (Grasselli, 2002). A desirable selective oxidation process must produce the desired products in high selectivity and high yield. This is a challenging task where the desired products are produced instead of carbon monoxide or dioxide, which are total combustion products and are thermodynamically more favorable (Kung, 1986).

1.2.1 Types of Selective Oxidation Reactions

Selective oxidation reaction can be classified into two types:

- i) Oxidative dehydrogenation
- ii) Partial oxidation

1.2.1.1 Oxidative Dehydrogenation

Dehydrogenation is a process in which a hydrocarbon molecule is converted into a more unsaturated hydrocarbon by breaking C-H bonds and forming C=C bonds (Kung, 1986). Catalytic dehydrogenation is introduced to convert paraffins to olefins. However the yields are low and there are some limitations (Centi *et al.*, 2001 and Nieto, 2006):

- i) Deactivation of catalyst by coke formation.
- ii) High operation temperature (973-1073 K) depends on paraffin.
- iii) Difficulties to separate alkenes from alkanes and by-products.

As the solution to the above problems, oxidative dehydrogenation was introduced. The advantages of oxidative dehydrogenation are (Centi *et al.*, 2001 and Nieto, 2006):

- i) Formation of water which overcome thermodynamically limitation.
