Abstract of the thesis presented to the Senate of Universiti Putra Malaysia in fulfillment of the requirements for the degree of Masters of Science

STRUCTURAL STRENGTH AND BEHAVIOUR OF CYLINDRICAL STEEL SHEET ROOFING

By

S. M. ZAHURUL ISLAM

December, 2005

CHAIRMAN: PROFESSOR ABANG ABDULLAH ABANG ALI

FACULTY: ENGINEERING

The roof does not only protect the building and its occupants from the effects of weather, but it is also an architectural feature that gives the building a desired appearance. Profiled steel sheet zincalume is normally used in roof as covering materials, without any attention paid to its structural capability as a self-supporting medium. A self-supporting roofing element is a new; where profiled sheeting roof could run continuous lengths of roof spans without internal support. This roofing system saves material and construction cost by avoiding internal support.

The aim of this research work is to study the possibility of using profiled steel sheet as self-supporting roofing elements for affordable housing. An analytical investigation using the finite element method was carried out on the structural strength and behaviour of different types of self-supporting roofing elements. Five laboratory tests using 3 m spans, 0.42 mm thickness and different crown heights of 1.5, 1.0, 0.50, 0.25 and 0.125 m specimens were conducted for assessing the structural strength and behaviour of roofing elements. Analytical study was carried out on the effect of shape, size, materials and support condition on the structural

behaviour of the selected roofing element. The analytical investigation was extended for longer spans to explore the feasibility of using of profiled steel sheet as a self-supporting roofing system in housing construction. In the analytical work, finite element models were generated and analyzed by using LUSAS software.

The analytical study for the roofing elements showed that parabolic profiled roofing element with crown height $1/6$ of span length was more efficient than others as a self-supporting element. The proposed self-supporting roofing element satisfied geometrical, buckling and material stability. Deflection was found to be the limiting criteria in design for self-supporting roofing element using profiled steel sheet. The presence of corrugation in the steel roofing element resulted in a significant improvement on the roof's structural performance compared to flat sheet element. Good agreement was found between the results from finite element analysis and those obtained experimentally. The FEM models predicted with a reasonable degree of accuracy the structural behaviour of different types of roofing elements. It was observed that a parabolic shape roofing element with an optimum crown height could be used as a self-supporting roofing element for about 4 m and 8 m span lengths using 0.42 mm and 1.25 mm thick profiled steel sheet. On the basis of this investigation, parabolic self-supporting roofing elements using profiled steel sheet with optimum crown height could be used in housing construction.

Abstrak tesis yang dikemukakan kepada Senat Universiti Putra Malaysia sebagai
memenuhi keperluan untuk ijazah Master Sains

**KEKUATAN STRUKTUR DAN KELAKUAN UNTUK BUMBUNG
KEPINGAN KELULI SILINDER**

OLEH

S. M. ZAHURUL ISLAM

Desember 2005

PENGERUSI: PROFESOR ABANG ABDULLAH ABANG ALI

FAKULTI : KEJURUTERAAN

Penutup bumbung bukan sahaja dapat melindungi bangunan dan penghuninya dari kesan cuaca tetapi ia juga memberi bentuk senibina yang dihendaki. Secara umumnya, kepingan besi beralun seperti zinalume digunakan sebagai bahan penutup tanpa mengambil kira kebolehan strukturnya untuk sokongan tersendiri. Elemen bumbung sokongan tersendiri terdiri daripada kepingan bumbung-bumbung yang dipasang tanpa sokongan dalam. Bumbung ini menjimatkan kos bahan dan pembinaan tanpa struktur sokongan dalaman.

Objektif utama penyelidikan ini ialah untuk membangunkan sistem bumbung yang mempunyai penyokong tersendiri untuk rumah kos rendah. Kajian secara analitik menggunakan kaedah unsur terhingga telah dijalankan ke atas kekuatan struktur dan kelakuan pelbagai jenis bumbung sokongan tersendiri. Lima ujian eksperimen telah dijalankan untuk menggunakan jarak 3 m, ketebalan 0.42 mm dan ketinggian 1.5, 1.0, 0.5, 0.25 dan 0.125 m untuk menilai kekuatan struktur dan kelakuan elemen penutup bumbung. Kajian analitikal secara terperinci telah dijalankan ke atas kesan bentuk, saiz, bahan-bahan dan keadaan penyokong untuk kekuatan struktur dan sifat-sifat elemen bumbung yang dipilih. Kajian analitikal telah dijalankan bagi jarak yang

lebih besar untuk menentukan kebolehan kepingan besi beralun sebagai bumbung sokongan di dalam pembinaan perumahan. Di dalam ujikaji analitikal ini, model unsur terhingga telah dijalankan dan dianalisis oleh perisian LUSAS.

Kajian analitikal untuk elemen bumbung berbentuk parabola dengan ketinggian puncak $1/6$ daripada jarak panjang didapati lebih efisien berbanding dengan yang lain sebagai unsur sokongan tersendiri. Bumbung sokongan tersendiri telah memenuhi kestabila geometric, buckling dan bahan. Pesongan telah didapati menjadi had rekabentuk bumbung sokongan tersendiri bagi kepingan besi beralun. Kehadiran bentuk beralun di dalam binaan elemen bumbung memberi kesan yang signifikan ke atas kekuatan struktur berbanding dengan elemen bumbung rata. Keputusan daripada analisis unsur terhingga adalah selaras dengan keputusan daripada makmal ujikaji. Model FEM menghasilkan jangkaan dengan kejituan yang tinggi terhadap sifat-sifat struktur pelbagai jenis elemen penutup bumbung. Keputusan menunjukkan bahawa elemen bumbung berbentuk parabola dengan ketinggian optimum boleh digunakan sebagai elemen bumbung sokongan tersendiri bagi jarak kepanjangann 4m hingga 8m dengan menggunakan 0.42 mm dan 1.25 mm tebal besi beralun. Hasil kajian mendapati bahawa elemen bumbung zinalume beralun sokongan tersendiri yang berbentuk parabolia dengan ketinggian lurah optimum boleh digunakan di dalam pembinaan perumahan.

ACKNOWLEDGEMENTS

The author would like to express his sincere appreciate and deepest gratitude to his supervisor, Prof. Ir. Abang Abdullah Abang Ali for his kind supervision, guidance, suggestions, encouragement and advices throughout the course of this project. Thanks and sincere appreciations are also goes to his co-supervisor, A special note of grateful thanks and deepest gratitude to his co-supervisor Associate Prof. Ir, Dr. Mohd Saleh Jaafar for his valuable guidance, suggestions and constructive comments towards this project. Thanks and sincere appreciations are also goes to his co-supervisor, Prof. Ir, Dr. Abdul Aziz Abdul Samad for his constructive comments and suggestion.

The author would also like to express his graduate to all colleagues, friend's laboratory technician En Halim Othman for his assistance and help throughout the duration of completing this project. The author would like to express his gratefulness to Haron Haji Tawil and Ng Kok Cheong, Technical Marketing Engineer, Blue Scope Lysaghat (Malaysia) Sdn Bhd for free supply of experimental test specimen.

The authors would like to thanks Housing Research Centre, UPM, Malaysia for valuable resources of research. The present work reported in this thesis is part of graduate research of Civil Engineering Department, UPM and the support of the National Research Programme on Affordable Quality Housing Account no. 54832 is gratefully acknowledged for financial support.

CHAPTER 1

INTRODUCTION

1.1 Background

The housing need in Malaysia is ever increasing due to rapid industrialization, urbanization, development and population explosion. Hence there is a growing awareness throughout the country among scientists, engineers, builders, designers and architects as well as developers to develop suitable low cost housing designs and bring down the cost of construction. The shortage of houses can be reduced to a greater extent by adopting new or alternative building materials or innovative construction techniques using conventional building materials. Due to the inadequacy of traditional building construction approach, new building systems started to appear at the beginning of the 20th century. Industrialised Building System (IBS) could provide a solution to the many problems in construction especially since the buildings constructed using this alternative method of construction have a shorter construction time and labour saving. The country is therefore looking for suitable alternatives to the conventional building approach to provide affordable quality housing to its citizens. Various programmes have been introduced to increase the housing stock in every country of the world, but the solution to the provision of affordable housing in sufficient quantity and quality for low-income strata of society has eluded many governments (Abang, 1994). Affordability is a term used to describe the relationship between income and effective demand of commodity. A “quality house” is one whereby the residents are happy and satisfied to live in while an “affordable house” is one, which do not create financial problems to the house owner.
