**Faculty : Science and Environmental Studies**

The pelagic fishery of Malaysia is of major economic importance because of its significant contribution to the country's fish production. This study employed four different sets of data in order to effectively model the impact of spatio-temporal characteristics of oceanographic changes on pelagic fishery in the Straits of Malacca (SOM). The study was divided into three components: (i) investigating the variations of temperature, salinity and dissolved oxygen; (ii) determining the status of small pelagic fishery resources; and (iii) modeling the impact of oceanographic changes, mainly the impacts of sea surface temperature (SST), on the distribution and abundance of pelagic fishery resources in the SOM.

The first component of this study investigated the spatio-temporal variability of physical oceanographic features, mainly sea temperature, salinity and dissolved

oxygen. Data sets from five Malacca Straits Research and Development Centre (MASDEC) oceanographic cruise expeditions conducted in the Straits of Malacca from 1998 to 2002 were rigorously analyzed. The sea surface temperature, salinity and dissolved oxygen in the SOM were found to respectively vary from 27.4 to 30.8 °C with mean ( $\bar{x}$ ) of 29.1 °C, 27.6 to 33.5 ppt with mean ( $\bar{x}$ ) of 31.6 ppt and 4.1 to 7.7 mg/L with mean ( $\bar{x}$ ) of 6.12 mg/L.

The second component of this research investigated the status of small pelagic fishery resources in the Straits of Malacca. Fish landing reflect fluctuating patterns in the catch trends. Such patterns can be categorized into: (a) fisheries which have shown increasing trends, including indian and indo-pacific mackerel (*Rastrelliger* spp.), selar scads (*Selar* spp.), Jack-cavalla-travelly (*Carangoides* spp.), mullets (*Mugilidae*), longtail tuna and kawakawa (*Thunnus tongol* and *Euthynnus affinis*), pomfrets (*Formio niger*, *Pampus* spp), and hairtails (*Trichiuridae*) (b) fisheries which have shown decreasing trends, including round scads (*Decapterus* spp.), anchovies (*Stolephorus* spp.), sardine (*Sardinella* spp.), hardtail scads (*Megalaspis cordyla*), spanish mackerel (*Scomberomorus* spp.), barracuda (*Sphyraena* spp.) and, wolf herring (*Chirocentrus dorab*). Moreover, despite some fluctuating trends, species like hardtail scads (*Megalaspis cordyla*), anchovies (*Stolephorus* spp.), spanish mackerel (*Scomberomorus* spp.), mullets (*Mugilidae*) and wolf herring (*Chirocentrus dorab*) have been decreasing right from the determined period whereas, species like Jack-cavalla-travelly (*Carangoides* spp.) showed declining trends only in the late 1990s.

The third component of the study determined the impacts of oceanographic changes, mainly the SST, on the distributions and abundance of pelagic fishery resource in the SOM. The annual fluctuations of the availability of pelagic fishery resources in relation to SST and Southern Oscillation Index (SOI) variations have been established. The natural environmental variations, known as El Niño Southern Oscillation (ENSO) events were identified as warmer than normal temperatures and with low negative values of the SOI. The periods 1979/80, 1982/83, 1987/88, 1991/92, 1993 and 1997/98 were identified as El Niño years whereas 1978, 1984/85, 1986, 1988/89, 1995/96 and 1999/2001 were identified as La Niña years.

Barracudas, round scads, Jack-cavalla-trevally, anchovies, hardtail scads and indian mackerel showed relatively low catch values during El Niño episodes. However, the catch of wolf herring and spanish mackerel were found to be comparatively high during El Niño episodes whereas mullets, selar scads, pomfrets, sardine, longtail tuna and hairtails did not show any significant difference during the El Niño/La Niña episodes. Annual landing of purse seine net operated in the SOM from 1980-2001 showed a significant ( $p<0.05$ ) correlation with SOI whereas the catch from trawl net did not show any apparent relationship.

Annual variability patterns between SST and Catch Per Unit Effort (CPUE) over the years showed a significant correlation indicating the CPUE to be high when the SST is high and vice versa. The results from the general linear modeling of the impacts of different SST levels and rainfall distribution on CPUE indicated that the SST was

found to be significantly ( $p<0.01$ ) correlated with the CPUE for both purse seine and trawl nets.

The physical oceanographic phenomenon has a significant impact on the variations of fish catches, CPUE and fish density. The concept and implications of SST variability and ENSO on distributions and abundance of pelagic fishery resources in the SOM were identified and critically discussed. Based on statistical analysis, the null hypothesis that oceanographic factors have no effect on pelagic fishery resources was subsequently rejected and the alternative hypothesis was accepted. The findings obtained from this research could be very useful for not only further development and management of pelagic fishery resources in the SOM but also all in tropical waters.

Abstrak tesis yang dikemukakan kepada Senat Universiti Putra Malaysia sebagai memenuhi keperluan untuk ijazah Doktor Falsafah

**TABURAN SUMBER PERIKANAN PELAGIK DI PERAIRAN SELAT MELAKA DAN PERKAITANNYA DENGAN PERUBAHAN SUHU**

**Oleh**

**Julai 2004**

**Pengerusi : Professor Mohd. Ibrahim Bin Hj. Mohamed, Ph.D.**

**Fakulti : Sains Dan Pengajian Alam Sekitar**

Perikanan pelagik Malaysia mempunyai kepentingan ekonomi yang besar kerana ia adalah salah satu sumbangan kepada pengeluaran ikan negara. Kajian ini menggunakan empat set data yang berbeza-beza untuk pemprosesan yg efektif terhadap kesan ciri-ciri spatio-temporal daripada perubahan oseanografik ke atas perikanan pelagik di Selat Melaka. Kajian ini terbahagi kepada tiga komponen iaitu: (i) menyelidik variasi daripada suhu, saliniti dan oksigen terlarut; (ii) menentukan status sumber perikanan pelagik kecil, dan (iii) menghasilkan model bagi kesan perubahan oseanografik, terutamanya kesan suhu permukaan air laut, terhadap taburan dan kelimpahan sumber perikanan pelagik di Selat Melaka.

Komponen pertama kajian ini telah mengkaji variabiliti spatio-temporal ciri-ciri fizik oseanografik, sebahagian besar mengenai suhu air, saliniti dan kandungan oksigen

terlarut. Lima ekspedisi laut MASDEC (Pusat Penyelidikan dan Pembangunan Selat Melaka) yang dijalankan dari tahun 1998 hingga 2002 telah menganalisis kaedah-kaedah ini secara menyeluruh. Suhu permukaan air laut, saliniti dan oksigen terlarut di Selat Melaka masing-masing antara  $27.4^{\circ}\text{C}$  hingga  $30.8^{\circ}\text{C}$  dengan purata ( $\bar{x}$ )  $29.1^{\circ}\text{C}$ ; 29.3 hingga 33.1 ppt dengan purata ( $\bar{x}$ )  $30.4 \pm 1.0$  ppt, dan 4.1 hingga 7.7 dengan purata ( $\bar{x}$ ) 6.12 mg/L.

Komponen kedua kejian ini telah mengkaji status sumber perikanan pelagic kecil di Selat Malaka. Ciri-ciri *dorata* ikan menunjukkan pola yang turunaik dalam tren tangkapan. Pola sedemikian dapat dikategorikan kepada (a) Perikanan yang menunjukkan tren peningkatan, termasuklah kembong (*Rastrelliger* spp.), aya (*Thunnus tongol* and *Euthynnus affinis*), selar kuning (*Selar* spp.), cermin (*Carangoides* spp.), belanak (*Mugilidae*), bawal hitam (*Formio niger*, *Pampus* spp) dan timah (*Trichiuridae*) dan (b) Tangkapan yg menunjukkan tren penurunan termasuklah selayang (*Decapterus* spp.), bilis/bunga air (*Stolephorus* spp.), tamban sisek (*Sardinella* spp.), cencaru (*Megalaspis cordyla*), tenggiri (*Scomberomorus* spp.), alu-alu (*Sphyraena* spp.) dan parang- parang (*Chirocentrus dorab*). Tamban pula, walaupun terdapat kadar turunaik yang tidak menentu, spesies seperti belanak (*Mugilidae*), cencaru (*Megalaspis cordyla*), bilis (*Stolephorus* spp.), parang- parang (*Chirocentrus dorab*) dan tenggiri (*Scomberomorus* spp.) telah menunjukkan penurunan dari awal lagi dalam tempoh kajian manakala spesies seperti cermin dan selar hanya menunjukkan penurunan pada akhir tahun 1990an.

Komponen ketiga kajian pula mengkaji kesan perubahan oseanografik, terutamanya suhu permukaan, taburan dan kelimpahan sumber perikanan pelagik di Selat Melaka. Turun naik tahunan padi keterdapatatan sumber perikanan pelagik sehubungan dengan perubahan pada suhu permukaan air laut dan Index Hayunan Selatan (SOI) telah ditentukan. Perubahan semulajadi alam sekitar yang dikenali sebagai peristiwa Hayunan Selatan El Niño (ENSO) telah dikenal pasti sebagai suhu persekitaran yang lebih tinggi dari suhu persekitaran normal dan dengan nilai negatif rendah Index Hayunan Selatan (SOI). Yang rendah dan negative jangkamasa 1979/80, 1982/83, 1987/88, 1991/92, 1993, dan 1997/98, telah dikenalpasti sebagai jangkamasa El Niño manakala jangkamasa 1978, 1984/85, 1986, 1988/89, 1995/96 dan 1999/2001 telah dikenalpasti sebagai jangkamasa La Niña.

Alu-alu, selayang, cermin, bilis, cencaru dan kembong secara relatifnya mempunyai kadar tangkapan yang rendah semasa berlakunya fenomena El Niño. Namun tangkapan ikan jenis parang-parang dan tenggiri adalah lebih tinggi semasa episod El Niño tetapi belanak, selar kuning, bawal, tamban sisik, aya (tongkol/hitam) dan timah tidak menunjukkan sebarang perubahan ketara dalam sepanjang episod El Niño atau La Niña. ‘Pukat jerut’ yang beroperasi di Selat Melaka dari tahun 1980-2001 menunjukkan korelasi yang ketara dengan SOI sedangkan tangkapan pukat tunda pula tidak menunjukkan sebarang hubungkait yang jelas.

Sejak bertahun-tahun membuat kajian mengenai pola perubahan bermusim antara suhu permukaan air laut dan Usaha Tangkapan Per Unit (CPUE), ia menunjukkan kolerasi yang ketara di mana apabila nilai CPUE tinggi maka suhu permukaan juga

turut tinggi dan sebaliknya jika suhu permukaan rendah. Keputusan pemodelan linear umum terhadap kesan mod suhu yg berbeza-beza permukaannya dan kadar taburan hujan ke atas CPUE menunjukkan bahawa suhu permukaan mempunyai kolerasi statistik yang ketara dengan CPUE untuk kedua-dua pukat jerut ('purse seine net') dan pukat tunda. Perbandingan hanya dilakukan untuk melihat kesan terhadap variasi tahunan suhu permukaan dan dari sini dapat dibuat kesimpulan bahawa hipotesis hubungan TPUU dengan suhu permukaan adalah kukuh. Walaupun begitu, pada masa ini, mekanisma hipotetikal yang menerangkan hubungan tersebut tidak dapat dijelaskan.

Fenomena oseanografik fizikal didapati mempunyai kesan penting terhadap variasi dalam penangkapan ikan, Usaha Tangkapan Per Unit (TPUU) dan kepadatan ikan. Konsep dan implikasi perubahan suhu permukaan laut dan Hayunan Selatan El Niño ke atas taburan dan kelimpahan perikanan pelagik yang dinamik di Selat Melaka telah berjaya dikenal pasti dan dibincangkan secara kritikal. Berdasarkan kepada analisis statistik, terdapat hipotesis yang kurang jelas yang menyatakan faktor-faktor oseanografik tidak memberi kesan ke atas sumber perikanan pelagik telah berjaya dibuktikan secara tidak sahih dan hipotesis alternatif telah diterima. Hasil yang diperolehi dari kajian ini amatlah berguna dalam perikanan pelagik di Selat Melaka.

## **ACKNOWLEDGEMENT**

**IN THE NAME OF ALLAH, THE MOST GRACIOUS, THE MOST MERCIFUL**

Bless be to Allah (S.W.), the Almighty who had created me and then gave me such an opportunity to conduct a research and to complete its report as my Ph.D. programme.

Numerous people are thanked for making this dissertation completed. In short, the following particulars have to be mentioned for their regular motivation through my tenure of study period.

First and foremost, ever lasting gratitude goes to the chairman of the supervisory committee, Professor Dr. Mohd. Ibrahim Hj. Mohamed, Director of Malacca Straits Research and Development Centre (MASDEC) whose constant supervision, valuable guidance and encouragement during my study are duly acknowledged. Similarly, I would like to extend my sincerest gratitude and completely wholehearted acknowledgements to the other members of the committee, namely Professor Dr. Hj. Mohd. Azmi Bin Ambak, Dean of Faculty of Science and Technology, University College of Science and Technology Malaysia and Associate Professor Dr. Abdul Rashid Mohamed Shariff, Head, Department of Biological and Agricultural Engineering, Faculty of Engineering, Universiti Putra Malaysia for their advice and comments during my study period.

I am very grateful and acknowledge the substantial financial support from the Islamic Development Bank (IDB), Jeddah, Saudi Arabia for offering me a Science and Technology Merit Scholarship, which enabled me to further my studies at Universiti

Putra Malaysia. Special thanks go to Dr. Mohd. Ghazali Bin Md Noor, Head of Scholarship Programme of the IDB and Dr. Ziad Salim, Science and Technology merit officer of the IDB for their understanding and assistance.

I acknowledge the contribution of Intensification of Research Priority Areas (IRPA) project no “0802040093” and the Department of Meteorological Services for providing sea surface temperature and rainfall data. In addition, I wish to acknowledge the use of some datasets on Ferret, a product of NOAA's Pacific Marine Environmental Laboratory.

Great acknowledgements and gratitude go to Dr. Hiroshiku Yanagawa, JICA expert for his contribution and guidance one way or another. My moral satisfaction and appreciation also go to Dr. Sanjoy and Mr. David Marioni for prove reading this thesis.

In addition, I also wish to express my appreciation to Mr. Abdel Galeel Ali Yousif, Mahamoud Hassan Tako, Muhiyadin Ibrahim Hassan, Ibrahim Shiekh Abdulkadir, Dr. Kabashi K. Kabashi, Dr. Ahmed Jalal Khan, Dr. Mohamed Abdullahi Nur, Eng. Abdullahi Ali Mohamed, Abdullahi Farah, Rozihan B. Mohamed and other colleagues who have tremendously contributed directly or indirectly to this report.

Last but not least, I wish to express my heartfelt gratitude to both my parents Mr. Gabobe Hassan and Mrs. Fatimah Ahmed Mohamoud, my beloved wife Ubah Nur Gesey, sons Khalid and Khadar and daughters Khatra and Khuluud for their moral support and encouragement rendered to me during all the period towards this substantial : ement.
