Abstract of the thesis presented to the Senate of Universiti Putra Malaysia in fulfillment of the requirement for the degree of Doctor of Philosophy

APPLICATION OF INTEGRATED SOLAR POND WITH EVAPORATION SYSTEM FOR HEAT GENERATION TO RECOVER MINERALS IN REJECTED BRINE

By

ABDULSALAM ABDULLAH N. ALREWASHED

August 2016

Chairman: Profesor Azni Idris, PhD Faculty : Engineering

Desalination plants are known to discharge large value of brine as waste from the distillation process which is increasing globally over time. Although the desalination techniques has a positive impact to the eco-socio and industrial sector by solving the problem of water shortage, it also contributes negatively to the environment during discharge of the concentrated brine back to the sea or landfill. However, the treatment of the brine could be effectively utilized by converting it into by-products via solar pond technology. Generation of heat using solar pond technology has certain limitations, but in case of Saudi Arabia all these limitations can be effectively addressed.

This research focused on the use of a solar pond with the integration of heat, power and the concentrated brine. The result from the characteristics of seawater and brine demonstrated that the level of mineral and salt in brine was very high compared to sea water. With respect to economic value of the minerals, it was found that a potential revenue of 18.46 billion USD/per year in brine at AL-Khobar desalination plant is from Na⁺, Mg²⁺, K⁺, Ca²⁺ and Cu²⁺. To recover minerals, evaporation pond used to evaporate water from brine with the integration of solar pond for heat generation. For the designing and fabrication of the solar pond, it was found that the maximum temperature of about 65°C could be generated from solar pond. The experiment on evaporation rate using the evaporation pond showed that the best temperatures were from 45 °C to 70 °C, where evaporation rate increases linearly over the increment of temperature. This temperatures are used for faster evaporation to make brine more concentrate which have about 5% moisture content. This moisture need to be dried further to meet salt market specification over the world, and produced salt could be used for multiple purpose.

This research used microwave oven for salt drying process which was powered by solar PV technique. For harvesting maximum radiation of PV tracking surface, it should be determine the angle of PV setup to use the output power for powering microwave

which required 700 watts power for operation. The gain made by this tracker relative to flat plate collector was 35% and 81% in the summer and winter solstice days, respectively. Four solar panels were set at 27 degree to obtain maximum output to operate the microwave. It was found that, microwave drying process achieved faster drying by 16 times compared to the conventional heating on an average. The research has shown the best concept of recovering minerals from brine, using the integrated solar pond with evaporation pond by utilizing a PV panel to powering microwave.

Abstrak tesis ini dikemukakan kepada Senat Universiti Putra Malaysia sebagai memenuhi keperluan untuk ijazah Doktor Falsafah

APLIKASI INTEGRASI KOLAM SOLAR BERSAMA SISTEM EVAPORASI BAGI MENJANA HABA UNTUK MENGGAMBIL GALIAN-GALIAN DALAM AIR GARAM BUANGAN

Oleh

ABDULSALAM ABDULLAH N. ALREWASHED

Ogos 2016

Pengerusi : Profesor Azni Idris, PhD Fakulti : Kejuruteraan

Kilang-kilang desalinasi sangat terkenal dengan pembuangan air garam dengan kuantiti yang besar sebagai sisa dari proses yang mana ia semakin bertambah di seluruh dunia dari masa ke semasa. Walaupun teknik desalinasi ada impak positif kepada sosio-ekonomi dan sektor industri dalam menyelesaikan masalah kekurangan air bersih tetapi ia juga menyumbang secara negatif kepada alam sekitar semasa pembuangan sisa kelaut atau tanah penambakan. Walau bagaimanapun, rawatan air garam boleh dibuat secara berkesan dengan menukarkan cara penghasilannya melalui teknik kolam solar. Penjanaan haba melalui kolam solar ada batasnya tetapi di Saudi Arabia semua batasan ini boleh di atasi dengan berkesan.

Kajian ini memfokus dalam penggunaan kolam solar untuk mengintergrasi penjanaan haba, tenaga, dan air garam pekat. Keputusan yang diperolehi dari ciri-ciri air laut dan air garam di dapati panas garam galian-galian yang sangat tinggi. Dari segi nilai ekonomi ,galian-galian seperti Na⁺,Mg²⁺, K⁺, Ca²⁺ dan Cu²⁺ yang didapati dalam air garam di kilang desalinasi Al-Khobar boleh menjana pendapatan sebanyak USD 18.46 Billion setahun. Untuk mengambil galian-galian ini, kolam evaporasi telah digunakan untuk mengeringkan air dari air garam dengan integrasi kolam solar untuk menjana haba. Dalam rekaan dan fabrikasi kolam solar, didapati suhu lebih kurang 65 deg C boleh dijana dari kolam solar. Eksperimen berhubung dengan kadar eveporasi menggunakan kolam evaporasi menunjukkan suhu yang paling baik ialah dari 45 deg C sampai ke 70 deg C di mana kadar evaporasi meningkat secara lurus dalam peningkatan suhu tersebut. Suhu ini telah diguna pakai untuk peningkatan evaporasi dalam menjadikan air garam lebih pekat di mana kelembapan adalah lebih kurang 5%. Kelembapan ini perlu dikeringkan lagi untuk mencapai spesifikasi pasaran dunia dan garam-garam yang diperolehi boleh dipelbagai gunaan.

Kajian ini mengunakan ketahur gelombang mikro untuk mengeringkan garam dengan menggunakan tenaga yang dijana dari penggunakan teknik PV solar. Untuk menuai radiasi maksima dari penjejakan lapisan PV, ia mesti menetapkan sudut letak PV untuk menggunakan kuasa luaran sebagai penjana tenaga bagi gelombang mikro yang

memerlukan 700 watt. Nilai tambah yang diperolehi dengan cara ini berbanding dengan dari menggunakan piring rata masing-masing 35% and 81% di musim panas dan sejuk. Empat panel solar telah digunakan dengan sudut 27 darjah untuk menghasilkan keluaran maksima dan mengoperasi gelombang mikro. Proses penggeringan menggunakan gelombang mikro dapat mencapai kekeringan 16 kali ganda lebih cepat jika dibandingkan dengan cara biasa. Kajian ini telah menunjukkan konsep yang paling baik untuk mengambil galian-galian dari air garam adalah dengan mengintegrasikan kolam solar bersama kolam evaporasi dengan menggunakan panel PV untuk menjana gelombang mikro.

ACKNOWLEDGEMENTS

I would like to extend my sincere gratitude to Allah and after this to my supervisor, Prof. Dr. Azni Idris, for his invaluable guidance and support throughout my candidature. His scholarly criticisms, scrutiny and suggestions kept me going against all odds. In addition, I would like to thank Prof. Dr. Thamer Ahmad, who always provided me valuable consultation. Dr. Amimul Ahsan was also very helpful throughout my study. The prompt replies and value adding comments from my supervisory committee helped me to retain the quality of research and complete it on time.

This research journey would not have been successful without the moral support of my mother and my immediate family. I would like to thank my wife Lamya, for her loyalty, love, emotional support and endurance. Appreciation also goes out to my friends for their support and caring throughout my academic career. Special thanks and appreciation also goes to the Saline Water Conversion Corporation (SWCC) and the Research and Development Center in Al-Jubail desalination and power plant, Saudi Arabia. They provided me the required facilities, financial support and the permission to conduct experiments in Al-Khobar power and desalination plant. I also express my deepest gratitude to King Abdullah Foreign Scholarship Program for supporting me during my PhD.

Finally, I would like to thank everybody who helped me in anyway to make my PhD, a journey of success.

I certify that a Thesis Examination Committee has met on 11 August 2016 to conduct the final examination of Alrewashed, Abdulsalam Abdullah N on his thesis entitled "Application of Integrated Solar Pond with Evaporation System for Heat Generation to Recover Minerals in Rejected Brine" in accordance with the Universities and University Colleges Act 1971 and the Constitution of the Universiti Putra Malaysia [P.U.(A) 106] 15 March 1998. The Committee recommends that the student be awarded the Doctor of Philosophy.

Members of the Thesis Examination Committee were as follows:

Helmi Zulhaidi bin Mohd Shafri, PhD

Associate Professor Faculty of Engineering Universiti Putra Malaysia (Chairman)

Salmiaton binti Ali, PhD Associate Professor Faculty of Engineering Universiti Putra Malaysia (Internal Examiner)

Luqman Chuah Abdullah, PhD Professor Faculty of Engineering Universiti Putra Malaysia (Internal Examiner)

Monzur Alam Imteaz, PhD

Associate Professor Swinburne University of Technology Australia (External Examiner)

ZULKARNAIN ZAINAL, PhD Professor and Deputy Dean School of Graduate Studies Universiti Putra Malaysia

Date: 28 September 2016

This thesis was submitted to the Senate of Universiti Putra Malaysia and has been accepted as fulfillment of the requirement for the degree of Doctor of Philosophy.

The members of the Supervisory Committee were as follows:

Azni Idris, PhD Professor Faculty of Engineering Universiti Putra Malaysia (Chairman)

Thamer Ahmad, PhD Professor Faculty of Engineering Universiti Putra Malaysia (Member)

Amimul Ahsan, PhD Senior Lecturer Faculty of Engineering Universiti Putra Malaysia (Member)

BUJANG KIM HUAT, PhD

Professor and Dean School of Graduate Studies Universiti Putra Malaysia

CHAPTER 1

INTRODUCTION

Recently, the rapid growth in human populations, increasing urbanization, industrial escalation, and commercial developments are causing some concern, and has resulted in a significant demand for potable water worldwide. This global development has led to the pollution of available water resources, degradation of natural sources, deforestation and climate change, resulting the global warming, all of which play a significant role to reduce average rainfalls (Apps and Price, 2013).

Many semi-arid and arid regions in the world are suffering from regular water shortages, which is detrimental towards economic, social, and human developments. However, the shortage of water is already prevalent in many regions around the globe, where more than one billion people do not have access to the potable water. It was also documented that 90% of infections and diseases in developing countries are transmitted through polluted water (Devabhaktuni et al., 2013). Furthermore, severe ecosystem damage may inquire if water abstraction rates exceed natural renewal rates, leading to a depletion or salinization of stocks, and land desertification (Lattemann and Höpner, 2008a). These have become a leading environmental concern, both at national and international levels. Therefore, to meet increasing demand and prevent damage to the ecosystems and the aquifers, water management practices need to be employed to mitigate water scarcity worldwide. In coastal regions, the desalination of seawater is the technology that is generally employed to alleviate the water shortage. It also should be in consideration that the worldwide production capacity is more than 74.8 million m³/d (19,762 MGD) (Pankratz, 2013).

Desalination of seawater separates saline seawater into two streams: a fresh water stream containing a low concentration of dissolved salts, and a concentrated brine stream (Khawaji et al., 2008). Hence, the desalination process has emerged as an essential source of fresh water, especially in the arid region. The highest number of seawater desalination plants could be found in the Arabian Gulf, which is a region responsible for 57% of the global daily production (DesalData, 2012). The maximum amount of desalinated water is produced in the Kingdom of Saudi Arabia (KSA) comparing other countries over the world which is about 18%, while the Gulf Corporation Council (GCC) produces 41% of total production in the world. Desalinated water production by KSA reaches 10 million cubic meters per day (Mm³/d). In the future, 1.6 Mm³/d need to be added on top of the current 9.8 Mm³/d. Thermal-based desalination processes, especially the Multi-Stage Flash (MSF) desalination, with a capacity of 5.6 Mm³/d, still play a dominant role in KSA, however, Multi Effective Desalination (MED) and Reverse Osmosis (RO), both consuming lesser amounts of energy, are fast becoming more popular (Ghaffour et al., 2014).

Despite the fact that the desalination of seawater is responsible for the provision of quite a number of benefits to people and the environment via its constant supply of high quality drinking water without damaging natural freshwater ecosystems, there is an underlying negative effect, especially to the environment, due to concentrated (brine) and chemical discharges, capable of decreasing the quality of coastal water and the marine ecosystem (Vidalis, 2010). Brine has the comparatively higher value of salinity, alkalinity, and temperature gradient compared to the seawater, and these factors are especially detrimental to the development of marine species, survival of larvae, and reproductive traits and breeding of marine organisms (Chang, 2015).

This research investigated the best alternative that could minimize the potential environmental impact caused by brine disposal and other chemical concentrates. It has been established that the use of solar pond could be an alternative towards the effective management of brine, energy generation, and desalination.

1.1 Demand for fresh water

The human population has been recorded significant growth in the past few decades, which could be attributed to the enormous supply of provisions such as food, discovery of new resources for fresh water, and increased number of settlements. This unexpected population growth creates problems, amongst them shortages of potable water, which is projected to be the most prevalent problem in the near future (Li et al., 2010).

The world average baseline consumption of fresh water is 300 L per day per person, which is equivalent to about 100,000 L of fresh water per person annually. However, higher demands from the Arabian Gulf region have always been common. For example, the demand for fresh water in Saudi Arabia was estimated to be over 3,000 million cubic meters of potable water per annum for 2010. This alone entailed that there is an urgent need to find new alternative sources of fresh water, which lead to desalination technology being employed extensively in KSA in particular, and the gulf region in general (Raut and Kulkarni, 2012).

The solutions to the water challenges involve the creation of alternatives to water sources, preferably inexpensive ones. Dams and artesian wells have traditionally been used to provide fresh water, but these sources of water could only produce insufficient or unpredictable quantities of water (Danoun, 2007). The creation of alternative sources of water is a significant issue at the global level. In this context, desalination plants are one of the most vital and valuable alternative resources for many countries around the globe.

1.2 Desalination

The need for fresh or potable water in many countries due to the shortages of natural resources. It is therefore necessary to plan and create new methods, such as desalination technologies, which will provide fresh water that is potable for humans and animals, and irrigation for agriculture (Raut and Kulkarni, 2012). Desalination plant removed salt from seawater, in order to making the water potable (Linares et al., 2014).

The identification of desalination as an alternative supply strategy for fresh water helps meet the ever-increasing demand of water. Desalination describes the removal of salts and non-ionic minerals from sea water sources to a level suitable for human consumption. The desalination process can treat a variety of existing water with 5,000-10,000 mg/L total dissolved solids (TDS) and seawater (~35,000 mg/L TDS) from different sources (Bashitialalshaeer et al., 2011).

Desalination is made up of two main processes, which are evaporation and condensation via the application of heat. Reverse osmosis (RO), multi-stage flash (MSF), and multi effect distillation (MED) technologies are used by the desalination plants. In the Gulf region, the thermal processes (MSF: multi-stage flash; MED: multi effect distillation) account for 90% of production, while the main process in Spain is reverse osmosis (RO), where 95% of plants utilizing this technology (Latteman and Höpner, 2008a). It was envisaged that RO and MSF accounted for 83.7% of worldwide desalination capacity in 2004 (McCormick, 2007). Basically, the technique behind desalination plants is to separate saline into two streams: the first produces low concentrations dissolved salt and inorganic material suitable for human consumption, while the second produces unwanted concentrated dissolved salt solution called brine. Desalination is currently recording an annual increment of 9.5%. However, rejected brine is a common problem encountered from desalination process, as it kills many marine organisms and pollutes the sea. It was discovered that reject brine has the potential of increasing the salinity of water and soil when disposed into both water and soil (El-Naas, 2011).

1.3 Reject Brine

Brine is the waste fluid discharge from a desalination plant, containing high concentration of salts and dissolved minerals. It is a highly concentrated waste product, consisting of everything that was removed from seawater to produce potable water (Danoun, 2007). Generally, brine might be rejected directly either in the ocean alongside or in the form of a combination of other byproducts. The discharged brine has the ability to change the salinity, alkalinity, and temperature (El-Naas, 2011), and it is much harmful to a marine environment (Latteman and Höpner, 2008b).

There are many brine disposal alternatives that are widely acceptable today. Most of them are being used or currently under investigation, however, these alternatives are site-specific. Hence, all disposal methods, from an environmental and economical point of view, have to be assessed based on their respective sites (Vidalis, 2010). Examples of disposal methods are included (Vidalis, 2010) deep aquifer injection, deep well injection, aquifer re-injection, discharge to wastewater treatment plants, discharge of sewage system, discharge to open land, reuse for agriculture or landscaping, discharge of inland surface water, and solar gradient ponds. Among these techniques, the solar gradient pond, also known as solar pond, seems to be the best option, based on the fact that it leads to many important applications while reducing damage to the environment. Remarkable research has been done on a solar pond for the last 50 years (Saifullah et al., 2012), and it is now applied in many countries, such as Israel, China, USA, India, and Australia (Akbarzadeh et al., 2009). Meanwhile, countries such as KSA and other Gulf nations are also actively engaged in solar ponds research.

1.4 Solar Ponds

A solar pond is a shallow body of water that serves as a solar collector, equipped with an integral heat storage that supplies thermal energy. There are two types of solar ponds, convective and non-convective. The former permits convection, but prevent evaporation, and is exemplified in a shallow solar pond. It consists of a large bag with a blackened bottom, and a sheet of plastic or glass on top. Solar energy heats the bag during the day, while at night hot water is pumped into a large heat storage tank to minimize heat loss

(Saifullah et al., 2012). A non-convective solar pond is a large shallow body of water with an average depth of 3 - 4 m, set up in a way that its temperature gradient is opposite to the ones normally observed, which allows for the collection of radiant energy into heat, up to 95 °C in the system.

There are three types of non-convective solar ponds, these are salinity gradient solar pond (SGSP), membrane solar pond, and polymer gel layers solar pond. SGSP is a pool of water ~1-5 m deep containing dissolved salts that stabilizes the density gradient. This is further divided into three layers, the upper layer which is known as the upper convective zone (UCZ) of the clear fresh water, it serves as the solar collector or receiver, followed by the lower convective zone (LCZ) with the highest salt concentration, also serving as the heat storage zone, and finally the non-convective zone (NCZ), which is much thicker and occupies more than half of the depth of the pond (Saifullah et al., 2012).

SGSP is the most eco-friendly of solar energy desalination systems, as it can be used for electricity generation, heating, and cooling. Generally, solar ponds could be used for thermal applications, due to its ability to store thermal energy for long periods of time. This stored energy can be used for low-temperature thermal applications, such as thermal desalination (Lisa, 2009; DSE Capital Projects, 2008; Bashitialalshaeer et al., 2011), greenhouse heating (Benli, 2013), process heating (Devabhaktuni et al., 2013), space heating (Raut and Kulkarni, 2012), and agricultural applications.

1.5 Recovery of minerals from the sea water desalination

The recovery of minerals from seawater desalination resulted in reduced production costs and increased revenues. The extraction of materials and brine conditioning for surface storage is another advantage of desalination plants, as it makes them environmentally friendly (IAEA, 2007). Brine rejected by the desalination units contained the concentrate form of all the sixty elements from the periodic table. The utilization of brine in appropriate processes could yield calcium, magnesium, sodium, potassium, chlorine, sulfate, and bromine, as well as sodium chloride (Husain and Al-Rawajfeh, 2009).

It is therefore preferable to have a mineral recovery process in the reverse osmosis (RO), multi-stage flash (MSF), and multi effected desalination (MED) techniques. Minerals recovery of such resources will be considered very attractive in KSA and the Gulf region, due to its limited natural resources. There are deficiencies in the quantities of a majority of these elements on the land, as they are expensive, especially potassium and sodium salts.

1.6 Problem Statement

As pointed out previously, the tremendous population growth and increasing pressure on the available water resources, mostly in the arid regions, led to the establishment of desalination technologies. These technologies are a step-forward towards the mitigation of the scarcity of water resources worldwide. The introduction of desalination technology and the increases in the number of desalination plants around the world due to the rising shortage of fresh water source has been associated with several negative environmental impacts, the most important of which is the discharge of concentrated brine into land or marine environment, resulting damage in arable land, coastal water quality, and marine life, and air pollutant emissions attributed to the energy demand of the processes (Das et al., 2014; Ahmad & Baddour, 2014; Naser, 2013).

However, limited efforts had been made to characterize large quantities of and assess the impacts of brine discharge into an ambient environment. A feasible approach, which holds considerable promise, is a salinity gradient solar pond (SGSP), because it is a form of renewable energy source that collects solar radiation and stores it in the form of thermal energy for long periods of time (Sakhrieh & Salaymeh, 2013). SGSP is a cost effective method with a considerably lower technical know-how. Therefore, this research was intended to highlight the treatment of discharged brine from desalination plants based on solar pond application, identify potential mineral recovery and enhancement options alongside the cost reduction considerations. Figure 1.1 shows the summary of the problem statement.

From the integrated solar pond in the evaporation process, important salts could be recovered which has potential economic value. Daily disposal of brine globally reaches 571.8 million m³/day which could be turn into revenue. However, this salt is not usable due to the moisture content in the salt, which not complies with the market standard (Geise et al., 2014). Due to this, it is necessary to dry moisture from the salt. If we use the dryer or heater for drying moisture, it needs a power source to operate the dryer but need to the expensive energy to dry. Using renewable sources to power up the dryer could reduce environmental impact (Devabhaktuni et al., 2013). This study used renewable energy for evaporation pond to speed up the evaporation of brine using heat exchanger and also microwave for salt drying which is more economical. It is necessary develop a model to know the maximum radiation to determine the PV setup angle and estimate output power for microwave. Choosing a method for fast drying makes it more practical for commercialization.

Figure 1.1: Summary of the problem statement

1.7 Research Objectives

The objectives of the research are:

- 1. Characterization of the sea water and the rejected brine from AL-Khobar desalination plant and update detailed assessment of the economic value of the rejected brine,
- 2. Assessment and evaluation of the integrated solar pond, fabrication, operation, and testing solar pond,
- 3. Simulation of the impact of generating heat in the integrated solar pond in the evaporation process with and without heat exchanger,
- 4. Radiation modeling and performance evaluations of fixed, single and double axes tracking surfaces: A case study for AL-Khobar city, Saudi Arabia,
- 5. Drying the remaining moisture in the salt after the evaporation by using a PVpowered microwave device.

1.8 Case Study

The study is conducted in KSA, because it has a large capacity of desalination inventory and sources for raw waste brine. The work was carried out at the Saline water Conversion Corporation (SWCC) at Al-Aziziyah, which is 10 km away from the city of Al-Khobar at the phase 3 section, in the coastal area of the eastern province in KSA.

1.9 Research Scope

This research explained the concept of the application of solar pond for the disposal of treated brine from desalination plants. Characteristics of seawater and disposal brine, and the economic value of rejected brine was investigated as well. A solar pond was designed, fabricated, operated, and tested to determine the stable temperature of generating heat. The effect of heat generated from solar pond in the evaporation process was investigated as well. A simulation that models a small-scale solar pond that comes equipped with a heater that was fabricated as the requirements of this work.

Solar radiation was studied in order to design a suitable PV system that provide electrical power to the microwave device that will be responsible for removing the moisture from the acquired salt post-evaporation. Furthermore, the performance of the solar tracking systems for the electrical power generated by the PV system was investigated for future works, as it might be a commercial endeavor at larger scales. However, in the context of this work, a tilted PV panel was fixed due to the small size of the solar pond, which helps keep the cost of the project low.

1.10 Contributions

The salinity gradient solar pond (SGSP) is an alternative solution to the indiscriminate disposal of brine onto land and sea by desalination plants, as it is a cost effective method with a considerably low technical know-how. Recent work involves the employment of solar ponds on its own to increase the evaporation rates of seawater, while the generated heat is utilized elsewhere. However, using the solar pond to increase the evaporation rate of the rejected brine from the desalination plant has not been under intense scrutiny. Drying these minerals are also a time consuming process, and afterwards, it still requires further refinements. This study reported the results of the application of solar pond for heat generation to enhance the rate of evaporation of rejected brine in the evaporation pond, which is novel in the context of the desalination plants of KSA. This part of this research aims to address objectives 2 and 3.

The recovered mineral was totally dried by a microwave device, powering from a PV system, as pointed out in objectives 4 and 5. Following objective 1, the characteristics of the minerals were analyzed by acquiring rejected brine from desalination plant as well as seawater, and also the economic value of the minerals from the rejected brine was calculated. Generally, this strategy will result in a significant economic advantage via the creation of jobs and decreasing the total cost of the desalination technique.

1.11 Thesis Organization

This thesis is divided into 9 chapters. Chapter 1 briefly introduces desalination and solar ponds, the global need for fresh water, the desalination technique, and its impact on the environment. Then, the application of solar pond for minimizing brine disposal is explained, followed by the possibility of mineral recovery from desalination plants, problem statements, objectives, scopes of the study, and the contribution of the work is presented.

Chapter 2 presents the reviews of the literatures associated with the general concepts of desalination, brine disposal and management, solar pond, mineral recovery, evaporation pond, solar radiation, and PV and microwave applications. Moreover, the modeling and simulation of solar pond equipped with an evaporation pond are presented.

Chapter 3 presents a detail of the materials and methods employed in this work. It also discusses the modeling, simulations, and experimental procedures and the subsequent analyses of the data.

Chapter 4 analyses the specifications of seawater, as well as rejected brine from the desalination plant and discuss the economic value of the minerals present in the brine.

Chapter 5 shows the results of operation of the fabricated small-scale solar pond for 60 days and 2-day tests.

Chapter 6 presents the impact of generated heat of the solar pond in the evaporation process simulated by a heater at different temperatures. The evaporation rate of a normal evaporation process and the one with the extra heat from the solar pond is compared.

Chapter 7 shows the results of solar radiation modeling and the amount of solar energy that can be harvested via fixed, single, and double-axes tracking surfaces in Al-Khobar city, Saudi Arabia.

Chapter 8 describes the assembly of a PV system that could power a microwave device that used to remove the remaining moisture in the salt post-evaporation.

Chapter 9 concludes the work and recommends future work in the context of industrial applications. The references and appendices are compiled at the end of the thesis, description about modeling, simulations, calculations and pictures of the different steps of practical sections of the work is illustrated in the appendices section.
