**EFFECTS OF PLANT HARVEST AGE AND PLANT PARTS ON
PYTOCHEMICAL COMPOUNDS OF *Andrographis paniculata*
(Burm. F.) Nees**

By

NOR ELLIZA BINTI TAJIDIN

January 2017

**Chairperson : Siti Hajar Ahmad, PhD
Faculty : Agriculture**

Andrographis paniculata (Burm. F.) Nees (hempedu bumi) is harvested from the wild or cultivated area, causing variations in quality and consistency of the plant extracts and active compounds. Variations in its bioactive compounds, andrographolide (ANDRO), neoandrographolide (NAG), 14-deoxy-11, 12-didehydroandrographolide (DDAG), especially due to harvest age and plant parts used affect medicinal properties of the plant. The objective of this study was to determine optimum harvest age and suitable plant parts for quality and consistency of phytochemical compounds in *A. paniculata*. In Experiment 1, seedlings were raised in a nursery, field transplanted at 8 weeks after sowing (WAS), and harvested at 14, 16, 18, 20 and 22 WAS. Plant growth, phytochemical compounds, and heavy metal contaminations were determined. In Experiment 2, optimum harvest age of 19 WAS that produced highest bioactive compounds were selected for further phytochemical compound analysis in different plant parts (leaves, stems, and aerials) of young and mature development stages. In Experiment 3, verification in metabolites, bioactive compounds in young and mature leaves, and also young leaves harvested at 14 to 22 WAS were conducted using proton magnetic resonance (^1H NMR) combined with multivariate analysis. The maximum increment rate in height and number of leaves and branches were at 16 and 22 WAS, respectively. Specific leaf area decreased by 41% as plant harvest age increased. Maximum ANDRO, NAG, and DDAG contents were obtained at 19, 18.5 and 18 WAS, respectively. Plant fresh and dry weights did not correlate with bioactive compounds. Total phenolic content increased by 17.6% from 14 to 19.06 WAS (36 to 42.36 mg GAE/100 g DW) and decreased by 3% until 22 WAS. Total flavonoid content showed a cubic relationship ($r^2 = 0.97$) with harvest age. Antioxidant activities, except for reducing power, were highest at seed formation stage. The chlorophyll content started to increase by 47.7% from 14 (3.54 mg/g) to 20 (5.23 mg/g) WAS, remaining constant until seed formation. Heavy metal contents were below the permissible limits of WHO. In Experiment 2, the leaves had a highest extraction yield, followed by aerial parts and stems. ANDRO was 56.2% in young compared to mature

plants. ANDRO of mature leaves (1.18 mg/g) and mature aerial parts (1.03 mg/g) were 87.1% and 62.7% higher, respectively, compared to mature stems (0.63 mg/g). The NAG content of mature stage was 2.9 times higher than young stage. Mature leaves have highest NAG compared to young aerial and young stems. DDAG in mature stems were lower than other plant parts. Total flavonoid content, hesperetin and DPPH free radical scavenging activity was highest at young stage while rutin, FRAP and reducing power were highest at a mature stage. No significant differences were recorded in contents of total phenolics, naringin, kaempferol, and glycosaponin, and scavenging activity of hydrogen peroxide in young and mature plants. Seven metabolites, ANDRO, NAG, DAG, glucose, sucrose, choline, and alanine, were identified. Principle component analysis (PCA) indicated clear discrimination between young and mature leaves. This discrimination was influenced by the presence of glucose, sucrose, NAG and choline in mature leaves compared to ANDRO and DAG in young leaves. Analysis using PC 1 and PC 2 of young leaves harvested from 14 to 22 WAS showed trajectory changes in metabolites. A loading plot confirmed differences in metabolic patterns of the groups. From regression analysis ANDRO, NAG and DAG were maximum at pre-flowering and early flowering stages while glucose and choline increased with harvest age. Thus, *A. paniculata* young leaves should be harvested at pre-flowering stage (19 WAS) to obtain maximum yield and phytochemical properties with minimal heavy metal contents.

Abstrak tesis yang dikemukakan kepada Senat Universiti Putra Malaysia sebagai memenuhi keperluan untuk ijazah Doktor Falsafah

**KESAN UMUR TUAIAN TANAMAN DAN BAHAGIAN TUMBUHAN
TERHADAP KOMPAUN FITOKIMIA BAGI *Andrographis paniculata*
(Burm. F.) Nees**

Oleh

NOR ELLIZA BINTI TAJIDIN

Januari 2017

Pengerusi : Siti Hajar Binti Ahmad, PhD
Fakulti : Pertanian

Kualiti kandungan kimia di dalam ekstraks tumbuhan *Andrographis paniculata* (Burm. f.) Nees yang dituai dari kawasan hutan berbeza dengan yang ditanam. Faktor utama yang mempengaruhi variasi kandungan andrografolid (ANDRO), neoandrografolid (NAG), and 14-deoxy-11, 12-didehydroandrografolid (DDAG) adalah umur tanaman dan bahagian tanaman yang berbeza. Objektif utama kajian ini ialah untuk menentukan umur tuaian tanaman dan bahagian tanaman yang sesuai untuk memastikan kestabilan kualiti kompaun kimia di dalam *A. paniculata*. Bagi Experimen 1, anak pokok dibesarkan di dalam nurseri sehingga berusia 8 minggu selepas disemai (MSS), kemudian dipindahkan ke ladang seterusnya dituai pada 14, 16, 18, 20 and 22 MSS. Pertumbuhan pokok, kompaun fitokimia dan kandungan logam berat ditentukan pada setiap peringkat umur tanaman. Umur tanaman pada 19 MSS dipilih untuk Experimen 2, kerana mengandungi kompaun fitokimia yang tinggi. Tanaman dibahagikan kepada bahagian muda dan matang, setiap bahagian terdapat daun, batang dan aerial. Experimen 3, variasi diantara daun muda dan daun matang, serta daun muda yang dituai pada 14 hingga 22 MSS kemudiannya dianalisa menggunakan resonan proton magnetik (^1H NMR) dan analisis multivariat. Kadar ketinggian pokok adalah maksimum pada minggu ke 16, manakala bilangan daun dan batang maksimum pada 22 MSS. Ketinggian pokok berkorelasi dengan bilangan daun ($r = 0.97$) dan batang ($r = 0.94$). Keluasan spesifik daun menurun sebanyak 41% dengan peningkatan umur tuaian tanaman. Kandungan ANDRO, NAG dan DDAG berada pada tahap maksimum apabila tanaman dituai pada 19, 18.5 dan 18 MSS. Analisa korelasi juga menunjukkan bahawa berat basah dan kering tidak mempunyai hubungan yang signifikan dengan ANDRO, NAG dan DDAG. Kandungan fenolik meningkat sebanyak 17.6% apabila tanaman dituai dari minggu 14 hingga minggu 19.06 (36 dan 42.36 mg GAE/100 g DW), kemudiannya kandungan fenolik menurun sebanyak 3% apabila tanaman dituai pada 22 MSS. Kandungan flavonoid menunjukkan hubungan kubik ($r^2 = 0.97$) dengan umur tuaian tanaman. Aktiviti antioksidan adalah ditahap maksimum pada peringkat pembentukan benih, kecuali

bagi kuasa penurunan. Dari minggu 14 kandungan klorofil (3.54 mg/g) meningkat sebanyak 47.7% dibandingkan dengan kandungan klorofil (5.23 mg/g) pada tanaman dituai minggu 20, kandungan klorofil berada pada tahap yang sama apabila penuaian dilakukan pada peringkat berbunga dan berbuah. Kesemua kandungan logam berat berada dibawah tahap yang dibenarkan oleh WHO. Untuk eksperimen kedua, hasil ekstrak daripada daun adalah tinggi diikuti oleh bahagian aerial dan batang. Kandungan ANDRO meningkat sebanyak 56.2% pada bahagian muda berbanding dengan bahagian matang. ANDRO pada bahagian daun (1.18 mg/g) dan aerial yang matang (1.03 mg/g) adalah meningkat sebanyak 87.1% dan 62.7% berbanding dengan bahagian batang matang (0.63 mg/g). NAG pada bahagian matang adalah 2.9 kali ganda lebih tinggi berbanding bahagian muda. DDAG pada batang matang adalah rendah berbanding bahagian tanaman yang lain. Jumlah kandungan flavonoid, hesperetin dan DPPH tinggi pada bahagian muda, manakala rutin, FRAP dan kuasa penurunan adalah maksimum apabila tumbuhan dituai pada peringkat pertumbuhan matang. Tiada perbezaan yang signifikan dicatatkan bagi kandungan fenolik, naringin, kaempferol, aktiviti pemerangkapan hidrogen peroksida dan glikosaponin pada peringkat pertumbuhan muda dan matang. Terdapat tujuh metabolit yang berjaya dikenalpasti iaitu ANDRO, NAG, DAG, glukosa, sukrosa, kholin and alanin. Prinsip analisis komponen (PCA) menunjukkan diskriminasi yang nyata diantara daun muda dan matang. Diskriminasi ini telah dipengaruhi oleh kandungan glukosa, sukrosa, NAG dan kholin yang terdapat pada daun matang. Sementara itu, daun muda pula didominasi oleh kandungan ANDRO dan DAG. Daun muda menunjukkan perubahan trajektori pada PC 1 dan PC 2 terhadap kandungan metabolit apabila dituai pada minggu ke 14 hingga minggu ke 22 MSS. Perbezaan pada corak kumpulan metabolit juga turut disahkan melalui plot loading. Analisis regrasi menunjukkan kandungan ANDRO, NAG dan DAG adalah optimum pada peringkat pra-berbunga dan berbunga manakala kandungan glukosa dan kholin meningkat seiring dengan umur tuaian. Oleh yang demikian, daun muda hendaklah dituai pada peringkat pra-pembungaan (19 MSS) bagi mendapatkan kadar pertumbuhan, hasil tanaman dan fitokimia yang tinggi serta kandungan logam berat yang minimum.

ACKNOWLEDGEMENTS

In the name of Allah SWT, The most Beneficent, The most Merciful. Praise be to ALLAH SWT and peace and blessings be upon Prophet Muhammad SAW his family, his companions and upon all other Prophets and Messengers.

This dissertation would not have been possible without the guidance and help of several individuals who in one way or another contributed and extended their valuable assistance in the preparation and completion of this study.

First and foremost, my utmost gratitude to my lovely supervisor, Assoc. Prof. Dr. Siti Hajar Ahmad for her enlightening, suggestions and patient guidance from preliminary to the end of this study. She has been my inspiration as I hurdle all the obstacles in completing this work. I am also grateful to Prof. Dr. Mahmud Tengku Muda Mohamed and Prof. Dr. Khozifah Shaari for being the committee members and for their generosity, patience, and steadfast support to complete this study.

I am extremely grateful to my husband for his unfailing love, and support, mentally and spiritually throughout this journey. You are my strength, my best friend, my other half and the love of my life. Through thick and thin, I will love you at your strongest and support you at your weakest. I am deeply indebted to my dearest family especially Mak and Abah, and parents in law who deserve special mention for their inseparable support and do'a. To my brothers, sisters, nephews and in laws thank you for being supportive and caring siblings.

It is my utmost pleasure to thank En. Salahudin Mohd. Raof, En. Azizul Isha and En. Azhar Othman, who always was ready to lend a hand during my labwork. I owe deepest gratitude to all my friends for all those advices, guidance, comments and explanation, thank you very much.

Last but not least, I would like to dedicate this thesis to my late grandmother and grandfather, opah and tok wan who kindly raised me with their caring and love. Both of you are always in my heart and in my do'a.

I certify that a Thesis Examination Committee has met on 17 January 2017 to conduct the final examination of Nor Elliza binti Tajidin on her thesis entitled "Effects of Plant Harvest Age and Plant Parts on Phytochemical Compounds of *Andrographis paniculata* (Burm.F.) Nees" in accordance with the Universities and University Colleges Act 1971 and the Constitution of the Universiti Putra Malaysia [P.U.(A) 106] 15 March 1998. The Committee recommends that the student be awarded the Doctor of Philosophy.

Members of the Thesis Examination Committee were as follows:

Uma Rani a/p Sinniah, PhD

Associate Professor
Faculty of Agriculture
Universiti Putra Malaysia
(Chairman)

Mohd Rafii bin Yusop, PhD

Professor
Institute of Tropical Agriculture & Food Security
Universiti Putra Malaysia
(Internal Examiner)

Siti Aishah binti Hassan, PhD

Associate Professor
Faculty of Agriculture
Universiti Putra Malaysia
(Internal Examiner)

Elhadi Yahia, PhD

Professor
Autonomous University of Queretaro
Mexico
(External Examiner)

NOR AINI AB. SHUKOR, PhD
Professor and Deputy Dean
School of Graduate Studies
Universiti Putra Malaysia

Date: 28 April 2017

This thesis was submitted to the Senate of Universiti Putra Malaysia and has been accepted as fulfillment of the requirement for the degree Doctor of Philosophy. The members of Supervisory Committee were as follows:

Siti Hajar binti Ahmad, PhD

Associate Professor
Faculty of Agriculture
Universiti Putra Malaysia

4.17	Relationship between plant age (weeks after sowing) and chlorophyll content. Solid line indicates a significant quadratic regression trend at $P \leq 0.05$, $n = 30$.	47
5.1	Extraction yield of young and mature development stages of <i>Andrographis paniculata</i> . The values are means of three replicates \pm SE. Different alphabets above each bar indicate significant differences at $P \leq 0.05$ using Tukey's HSD test.	55
5.2	Extraction yield of leaves, stems and aerial plant parts at young and mature development stages of <i>Andrographis paniculata</i> . The values are means of three replicates \pm SE. Different alphabets above each bar indicate significant differences at $P \leq 0.05$ using Tukey's HSD test. Means for each plant parts nested within two development stages for each treatment.	56
5.3	Andrographolide content of young and mature development stages of <i>Andrographis paniculata</i> . The values are means of three replicates \pm SE. Different alphabets above each bar indicate significant differences at $P \leq 0.05$ using Tukey's HSD test.	57
5.4	Andrographolide contents of leaves, stems and aerial plant parts at young and mature development stages of <i>Andrographis paniculata</i> . The values are means of three replicates \pm SE. Different alphabets on above each bar indicate significant differences at $P \leq 0.05$ using Tukey's HSD test. Means for each plant parts nested within two development stages for each treatment.	57
5.5	RP-HPLC profile of mature leaves (A), young leaves (B), mature stems (C) young stems (D), mature aerial part (E) and young aerial part (F). Peaks andrographolide (1) and neoandrographolide (2).	58
5.6	Neoandrographolide content of young and mature development stages of <i>Andrographis paniculata</i> . The values are means of three replicates \pm SE. Different alphabets above each bar indicate significant differences at $P \leq 0.05$ using Tukey's HSD test.	59
5.7	Neondrographolide content of leaves, stems and aerial plant parts at young and mature development stages of <i>Andrographis paniculata</i> . The values are means of three replicates \pm SE. Different alphabets above each bar indicate significant differences at $P \leq 0.05$ using Tukey's HSD test. Means for each plant parts nested within two development stages for each treatment.	59
5.8	Contents of 14-deoxy-11, 12-didehydroandrographolide of young and mature development stages of <i>Andrographis paniculata</i> . The values are means of three replicates \pm SE. Different alphabets above each bar indicate significant differences at $P \leq 0.05$ using Tukey's HSD test.	60

- 5.9 Contents of 14-deoxy-11, 12-didehydroandrographolide of leaves, stems and aerial plant parts at young and mature development stages of *Andrographis paniculata*. The values are means of three replicates \pm SE. Different alphabets above each bar indicate significant differences at $P \leq 0.05$ using Tukey's HSD test. Means for each plant parts nested within two development stages for each treatment. 60
- 5.10 RP-HPLC profile of mature leaves (A), young leaves (B), mature stems (C), young stems (D); mature aerial part (D) and young aerial part (F). Peaks 14-deoxy-11, 12-didehydroandrographolide (1). 61
- 5.11 Total phenolic content of young and mature development stages of *Andrographis paniculata*. The values are means of three replicates \pm SE. Similar alphabets above each bar indicate not significantly different at $P \geq 0.05$ using Tukey's HSD test. 63
- 5.12 Total phenolic content of leaves, stems and aerial plant parts at young and mature development stages of *Andrographis paniculata*. The values are means of three replicates \pm SE. Different alphabets above each bar indicate significantly different at $P \leq 0.05$ using Tukey's HSD test. Means for each plant parts nested within two development stages for each treatment. 64
- 5.13 Total flavonoid content of young and mature development stages of *Andrographis paniculata*. The values are means of three replicates \pm SE. Different alphabets above each bar indicate significantly different at $P \leq 0.05$ using Tukey's HSD test. 65
- 5.14 Total flavonoid content of leaves, stems and aerial plant parts at young and mature development stages of *Andrographis paniculata*. The values are means of three replicates \pm SE. Different alphabets above each bar indicate significantly different at $P \leq 0.05$ using Tukey's HSD test. Means for each plant parts nested within two development stages for each treatment. 65
- 5.15 Chlorophyll content of young and mature development stages of *Andrographis paniculata*. The values are means of three replicates \pm SE. Different alphabets above each bar indicate significant differences at $P \leq 0.05$ using Tukey's HSD test. 73
- 5.16 Chlorophyll content of leaves, stems and aerial plant parts at young and mature development stages of *Andrographis paniculata*. The values are means of three replicates \pm SE. Different alphabets above each bar indicate significant different at $P \leq 0.05$ using Tukey's HSD test. Means for each plant parts nested within two plant development stages for each treatment. 73

- 5.17 Glycosaponin content of young and mature development stages of *Andrographis paniculata*. The values are means of three replicates \pm SE. Similar alphabets above each bar indicate not significantly different at $P \geq 0.05$ using Tukey's HSD test. 75
- 5.18 Glycosaponin content of leaves, stems and aerial plant parts at young and mature development stages of *Andrographis paniculata*. The values are means of three replicates \pm SE. Different alphabets above each bar indicate significant differences at $P \leq 0.05$ using Tukey's HSD test. Means for each plant parts nested within two development stages for each treatment. 76
- 6.1 2D *J*-resolved spectra of the *Andrographis paniculata* extract in the region δ 0.0 to 8.8 ppm. The observed signals are as follows: andrographolide (1), neoandrographolide (2), and 14-deoxyandrographolide (3). 81
- 6.2 Full ^1H NMR spectra of young and mature leaves of *Andrographis paniculata*, from δ 0.0 to 8.0 ppm. Peaks andrographolide (1), neoandrographolide (2), 14-deoxyandrographolide (3), glucose (4), sucrose (5), alanine (6), and choline (7). 83
- 6.3 Full ^1H NMR spectra of young leaves of *Andrographis paniculata*, harvested at 14, 16, 18, 20 and 22 weeks after sowing (WAS) from δ 0.0 to 8.0 ppm. Peaks andrographolide (1), neoandrographolide (2), 14-deoxyandrographolide (3), glucose (4), sucrose (5), alanine (6), and choline (7). 84
- 6.4 Principle component analysis of young and mature leaves using PC 1 and PC 2 (a). The loading plot represents the discrimination of metabolites between young and mature leaves of *Andrographis paniculata* (b). 86
- 6.5 Peak area of ^1H NMR signals of selected metabolites in young and mature leaves of *Andrographis paniculata*. Mean values \pm SE were from five replications. Different alphabets above each bar indicate significant differences at $P \leq 0.05$ using LSD test. 87
- 6.6 Principle component analysis of PC 1 and PC 2 showed the trajectory of each sample harvested at 14, 16, 18, 20 and 22 weeks after sowing. Dashed arrow indicated the order of plant harvest ages (a). The loading plots of metabolites for the first two principle components, PC 1 and PC 2 (b). 89
- 6.7 Relationships between plant harvest age (week after sowing) and peak area of ^1H NMR signals of andrographolide (a), neoandrographolide (b), 14-deoxyandrographolide (c), glucose (d), sucrose (e), and choline (f). Solid line indicates a significant quadratic regression trend at $P \leq 0.05$. 90

LIST OF ABBREVIATIONS

μm	Micrometer
$^{\circ}\text{C}$	Degree Celsius
g	Gram
mL	Millilitre
h	Hour
mg	Milligram
min	Minute
%	Percentage
mm	Millimetre
RP-HPLC	Reversed phase - high performance liquid chromatography
hPa	Hectopascals
μL	Microliter
rpm	Revolutions per minute
N	Normality
ppm	Parts per million
nm	Nanometer
w/v	Weight per volume
mM	Millimolar
M	Molarity
$\mu\text{g/mL}$	Microgram per millilitre
$\mu\text{g/g}$	Microgram per gram
w/w	Weight per weight
PP	Plant part
PS	Plant stage
SE	Standard error

DW	Dry weight
mg/g	Milligram per gram
ANDRO	Andrographolide
NAG	Neoandrographolide
DDAG	14-deoxy-11, 12-didehydroandrographolide
DAG	14-deoxyandrographolide
DPPH	2,2-diphenyl-1-picrylhydrazyl
FRAP	Ferric reducing antioxidant power
H ₂ O ₂	Hydrogen peroxide
ROS	Reactive oxygen species
¹ H NMR	Proton nuclear magnetic resonance
PCA	Principle component analysis

CHAPTER 1

INTRODUCTION

The use of herbal plants as alternative medicines has tremendously increased in the past decade and become a public interest. It is estimated that nearly four billion people around the world rely on herbal products as alternatives to modern medicines for primary source of healthcare (Ekor, 2013). The annual worldwide market income generated from this herbal industry is approximately US\$60 billion (Wachtel-Galor and Benzie, 2011; Tilburt and Kaptchuk, 2008). There are several factors that influence public interest in herbal remedies: (i) efficiency or effectiveness of medicinal herbs, (ii) preference of consumers for natural remedies (iii) low cost and minimal side effect compared with modern medicines (iv) easily available and (v) for treating self-diagnosed disorders or symptoms (Ekor, 2013; Bandaranayake, 2006).

There are 18 herbal plants that have been selected under the National Key Economic Area (NKEA) research grant schemes, and one of them is the *Andrographis paniculata* (Burm. f.) Nees. (MOA, 2012). *A. paniculata* is an herbaceous plant that belongs to the Acanthaceae family (Mishra et al., 2014), widely found and cultivated in tropical and subtropical Asia and India (Benoy et al., 2012). *A. paniculata* has a wide range of medicinal and pharmacological applications. Traditionally, *A. paniculata* extract from the aerial parts are used to get rid of body heat, dispel toxins from the body, prevent common cold and sinusitis (Joselin and Jeeva, 2014), fever, and as well as an antidote against snake and insect poisons (Samy et al., 2008). Most of the *A. paniculata* products available in the market were highly consumed as stomachic, hepatoprotective, dyspepsia, anthelmintic and bitter tonic (Kataky and Handique, 2010).

According to Valdiani et al. (2012), the price of superior quality dried *A. paniculata* leaves were US\$5 per kg, while the purified bioactive compounds such as andrographolide (ANDRO) and its derivatives, could be sold for US\$100,000.00/kg (Valdiani et al. 2012). The consumption of aerial *A. paniculata* in India is around 250 tonnes/year (Pholphana et al., 2013; Sharma et al., 2008). There is a large market demand for raw plant materials and extracts of *A. paniculata*. The production of *A. paniculata* in Malaysia is only 1 tonne/year (DOA, 2014) and Malaysia is importing 70% of herbal products, including *A. paniculata*, to meet the local demand (Mohd Noor and Sukir, 2000). Conversely, the production of wild growing *A. paniculata* in India is estimated to be 5000 tonnes/year (Kumar and Kumar, 2013).

Several researches on *A. paniculata*, that focused on the reproductive systems and genetic variations (Chia, 2009; Abdalla, 2005; Biffa, 2003), crossability and genetic analysis (Valdiani, 2012), and salt stress (Talei, 2012), have been conducted in Malaysia. According to Biffa (2003), about 26 accessions of *A. paniculata* have been collected around the Peninsular of Malaysia from April to June, 2002. Among the 26 accessions, only five accessions (11179S, 11269P, 11265P, 11261P and 11284P) had

been shortlisted as promising (Abdalla, 2005; Biffa, 2003). Accessions 11265P was selected and named as 'Harapan' due to the beneficial morphological traits (Biffa, 2003) and phytochemical constituents (Abdalla, 2005) with the potential to be commercialized in Malaysia.

The selection of a potential plant accession, variety or cultivar has been based on growth performance, yield and quality of the plant material. However, environmental effects, pest infestation, diseases, weeds (Chanli, 2012), and agronomic practices, especially plant harvest age and plant parts used (Chen et al., 2012) need to be studied. Plant harvest age and plant parts are important factors that influence the phytochemical properties of a herbal plant (Raya et al., 2015; Couto et al., 2013). Since *A. paniculata* is categorized under an angiosperm plant, most of the studies have stated that changes in phenological stage affect the growth characteristics and phytochemical contents of the plants (Ahl and Sabra, 2016; Ben Farhat et al., 2015; Chauhan et al., 2013; Chen et al., 2012; Chouaieb et al., 2012). According to Fenner (1998), the phenology of growth and reproduction in plants are influenced and closely related to the abiotic and biotic factors. Several recommendations, mostly from India, China and Thailand, where the geography, climate and weather condition are different from Malaysia, have been reported on the suitable harvesting age or stage of *A. paniculata*. (Pholphana et al., 2013; Kumar and Kumar, 2013; Parashar et al., 2011; Singh et al., 2011; Pandey and Mandal, 2010). There is a lack of information on the optimum plant harvest age of Harapan (11265P).

Plant parts are a major factor that influences the phytochemical properties of a plant extract (Couto et al., 2013; Pholphana et al., 2013; Gajbhiye and Khristi, 2010; Zhao et al., 2007). A study conducted on *Clinacanthus nutans* reported that plant parts and vegetative stage did influence the bioactive compounds of the plant (Raya et al., 2015). Panawala et al. (2016) also claimed that plant parts and development stage also affected the overall quantity of phytochemical properties of *Pimenta dioica* (L.) Merr. The aerial plant parts (leaves and stems) of *A. paniculata* are normally used for the extraction of bioactive compounds and phytochemicals, and each compound possessed different potency in pharmacological activities (Thisoda et al., 2006). Normally, farmers harvest the whole aerial parts in order to obtain a higher biomass yield, which is dominated by the weight of the stems. Since the contribution of stems to the final herbage is substantial and amount of bioactive compounds present in stems could change the final concentration of ANDRO, NAG and DDAG, it becomes vital to study the distribution of this bioactive compound in the different plant parts in order to control the quality of the final crude extract.

Nowadays, metabolomic is gaining much attention among scientists since it is a holistic, non-biased method and could provide comprehensive, qualitative and quantitative overview of the metabolites present in the plant (Shuib et al. 2011). By using ^1H NMR and multivariate analysis, the results obtained could provide information about metabolic fingerprints, detect chemical variations and provide a possible explanation of discrimination between the metabolomes in the plant extracts (Mediani et al., 2015; Khoo et al., 2015). However, there is no information available on the variation in the metabolic discrimination of young and mature plant parts of *A.*

paniculata at different harvest age using advanced tools, such as the ^1H NMR and multivariate analysis.

Since Harapan is a recommended accession to be commercialized in Malaysia, therefore studies on plant harvest age and plant parts should be carried out in order to achieve optimum growth and high phytochemical contents for production of superior quality plant extract that could meet international quality standards. Thus, the main objective of this study was to determine optimum plant harvest age and suitable plant parts for superior quality and consistency of phytochemical compounds in *A. paniculata*. The specific objectives were as follows:

1. To determine the effects of plant harvest age on growth characteristics, phytochemical compounds, and heavy metal contents of *A. paniculata*.
2. To compare the phytochemical properties of different plant parts of *A. paniculata* when harvested at young and mature development stages.
3. To discriminate young versus mature leaves and explore the changes in the metabolites profile of young leaves harvested at different harvest age/stage.
