SYNTHESIS AND CHARACTERISATION OF JATROPHA OIL-BASED WATER-BORNE POLYURETHANE DISPERSIONS

By

SARIAH BINTI SAALAH

March 2016

Chairman : Professor Luqman Chuah Abdullah, PhD
Faculty : Engineering

The transition from solvent-borne to waterborne polyurethane (PU) coatings is driven by the stringent regulations to reduce emissions of volatile organic compounds (VOCs) from the products, enhanced by the increasing awareness of the consumers of safety and health issues. On the other hand, a low cost, abundant, and renewable vegetable oil source is now receiving increasing attention for polyurethane production. Previous studies reported the possibility of the production of PU coatings, adhesives and elastomers from non-edible jatropha oil. However, as far as is known, no study has reported on waterborne PU synthesis from jatropha oil. In this research, jatropha oil is modified to polyol to be used as a starting material for the production of a waterborne PU dispersion. A series of jatropha oil-based polyols (JOLs) were synthesised from jatropha oil by a two-step process, namely epoxidation and oxirane ring opening. The effect of epoxidation conditions on the properties of the JOLs was investigated. The JOLs are liquid under room conditions with a hydroxyl number in a range of 138 to 217 mg KOH/g.

The jatropha oil-based waterborne polyurethane (JPU) dispersions were produced by polymerising the JOLs with isophrene diisocyanate (IPDI) and dimethylol propionic acid (DMPA). The colloidal stability of the resulting JPU dispersions were studied by particle size analysis and rheology measurements. Inclusion of up to 5.4 wt.% of DMPA as an internal emulsifier produced a wide range of particle sizes from 84 nm to 825 nm. However, further increasing the DMPA content up to 6.8 wt.% resulted in smaller particles but a multimodal particle size distribution was obtained for the dispersion synthesised from low OH number polyol. The dispersions have a solid content of 22.9 to 26.9 wt.% with a relatively low viscosity in the range 5.6-53.1 mPa.s. The JPU dispersions exhibited the typical flow behaviour of the commercial polyurethane dispersions, ranging from almost Newtonian to a shear thinning fluid, and the experimental data correlated well with the Cross model. The samples were stable after 18 months of storage under room conditions.

A films with up to 62 wt.% bio-based content were successfully produced after evaporation of water from the JPU dispersion. The chemical, physical, mechanical and thermal properties of the films were characterised. The experimental data revealed that the OH number of the JOLs, DMPA content and the hard segments were the key parameters which control the structure and the properties of the JPU films. The JPU film derived high OH number polyol and high hard segment content exhibited the highest crosslinking density. This contributed to higher hardness, better mechanical properties, and hydrophobic surface character. The films show an elastomeric polymer behaviour and good thermal stability.

The JPU dispersions were applied on a wood surface and the performance of the coatings were evaluated. The JPU films have excellent adhesion to the substrate, excellent optical properties as well as chemical and abrasion resistance. The PU dispersions synthesised in this work possess good properties with a promising application as a standalone coating or binder for wood and decorative coatings.

SINTESIS DAN PENCIRIAN DISPERSI POLIURETANA BERBASIS AIR YANG BERASASKAN MINYAK JATROPHA

Oleh

SARIAH BINTI SAALAH

Mac 2016

Pengerusi : Profesor Luqman Chuah Abdullah, PhD
Fakulti : Kejuruteraan

Peralihan daripada poliuretana (PU) berbasis pelarut kepada dispersi PU berbasis air adalah didorong oleh peraturan ketat untuk mengurangkan pembebasan sebatian organik meruap (VOC) daripada produk, ditambah pula dengan peningkatan kesedaran pengguna mengenai isu-isu keselamatan dan kesihatan. Minyak sayuran yang merupakan sumber boleh diperbaharui dan boleh diperolehi dengan harga yang murah kini mendapat perhatian utama dalam penghasilan PU. Kajian lepas mendapati minyak jatropaha boleh digunakan untuk membuat bahan penyalut, perekat dan elastomer. Walaubagaimanapun, tiada kajian dilaporkan mengenai pembuatan dispersi PU berbasis air daripada minyak jatropaha. Dalam kajian ini, minyak jatropaha diubah suai kepada polioliol untuk digunakan sebagai bahan untuk pembuatan PU berbasis air. Satu siri polioliol telah dihasilkan melalui dua langkah, iaitu pengepoksidaan dan pembukaan cincin oksiran. Kajian dilakukan untuk mengenalpasti kesan kondisi epoksidasi terhadap sifat polioliol yang dihasilkan. Hasil ujikaji mendapati semua JOL bersifat cecair pada keadaan bilik dengan nilai nombor hidroksil antara 138 hingga 217 mg KOH/g.

Dispersi PU berbasis air yang berasaskan minyak jatropaha (JPU) telah berjaya dihasilkan melalui tindak balas pempolimeran antara JOL dengan isoprena diisiosianat (IPDI), dan dimetilol asid propionik (DMPA). Kestabilan koloid JPU dalam air dikaji melalui analisis saiz partikel dan juga reologi. Penambahan sehingga 5.4% DMPA sebagai pengemulsi dalaman menghasilkan pelbagai saiz partikel daripada 84 nm hingga 825 nm. Apabila kandungan DMPA ditingkatkan sehingga 6.8 %, partikel yang lebih kecil terhasil tetapi beberapa mod taburan saiz partikel telah diperolehi bagi JPU yang disintesis daripada polioliol dengan nombor OH yang rendah. Semua JPU ini disediakan dengan kandungan berat pepejal 22.9-26.9 %, dan kelikatan yang rendah dalam julat 5.6-53.1 mPa.s. JPU ini mempamerkan kelakuan dispersi poliuretana komersial, iaitu sama ada hampir Newtonian atau *shear-thinning*, dan data eksperimen ini boleh diwakili oleh model Cross. Sampel JPU didapati stabil di bawah 18 bulan penyimpanan pada keadaan bilik.

Filem yang mengandungi sehingga 62% berat kandungan berasaskan bio telah berjaya dihasilkan selepas air disejatkan dari dispersi JPU. Ini menunjukkan kebolehan pembentukan filem yang baik. Sifat-sifat kimia, fizikal, mekanikal dan haba filem yang terhasil telah ditentukan. Data eksperimen menunjukkan bahawa kandungan kumpulan berfungsi OH pada JOL, DMPA dan segmen keras adalah parameter utama yang mengawal struktur dan sifat-sifat filem JPU. Filem yang disintesis daripada polioliol yang memiliki nombor OH tertinggi dan juga tinggi kandungan segmen kerasnya mempamerkan ketumpatan silang yang paling tinggi, seterusnya menyumbang kepada kekerasan yang lebih tinggi, sifat mekanikal yang lebih baik, dan mempamerkan permukaan hidrofobik. Semua filem JPU mempamerkan kelakuan polimer lentur mempunyai kestabilan terma yang tinggi.

Dispersi JPU berbasis air telah digunakan sebagai bahan pelapis untuk kayu dan prestasi lapisan tersebut dinilai. JPU juga melekat sempurna terhadap substrat kayu. Selain itu, lapisan tersebut mempamerkan ciri-ciri optik yang sangat baik, begitu juga dengan rintangan kimia dan rintangan lelasannya. Keseluruhannya, dispersi JPU berbasis air yang telah disintesis dalam kajian ini mempunyai ciri-ciri yang baik dan berpotensi digunakan sebagai bahan pelapis atau pengikat untuk formulasi bahan pelapis kayu dan hiasan.

ACKNOWLEDGEMENTS

First and foremost, I thank to Allah s.w.t., the Almighty, for granting me countless blessings, guidance and knowledge to complete this work. I would like to express my sincerest gratitude and appreciation to my supervisor, Professor Dr. Luqman Chuah Abdullah, who has supported me with his continuous trust, motivation and guidance throughout this study. Without his constant encouragement this thesis would not have been completed or written. I am also in debt to my excellent supervisory committee, Professor Dr. Mahiran Basri, Dr. Min Min Aung, Dr. Mekzah Salleh and Dr. Dayang Radiah Awang Biak for their extensive guidance, comments and suggestions which were very precious for this research work.

My sincere appreciation also goes to staffs in the Radiation Processing Technology Division of Malaysia Nuclear Agency, Dr. Nik Ghazali, Ms Rida, Mr Rosli, Mr Hasnul, Mr Zahid and Mr Wan for their full-cooperation during my study. Many thanks also to Mr. Raman at Faculty of Engineering Lab for his assistance on rheometer instrument. Special thanks to my graduate fellows, Emiliana Rose, Rabiatul Adawiyah, Suhaini, Siti Hasnah, Saba Rashidi and Syeed Saifulazry for their company, support and encouragement which has made my graduate studies an exciting and fulfilling journey.

I must acknowledge the Ministry of Higher Education (MOHE), Malaysia and Universiti Malaysia Sabah (UMS) for giving me the financial support and opportunity to pursue my PhD study in Universiti Putra Malaysia. I would also like to extend my appreciation to Malaysia Nuclear Agency for the use of their chemicals and facilities.

Finally, I would like to extend my gratitude to my beloved husband, Dahlan, my dearest sons, Luqman Hamiz and Lutfi Hanif, beloved parents, Saallah and Samira, dearest brothers and sisters, Suryani, Herman, Herwan, Sharinee and Shahira. Their unconditional love, encouragement, support and prayers were the driving force that inspired me to succeed and build my strength and confidence to overcome the many seemingly insurmountable obstacles in life. Their principles and guidance showed the way.

I certify that a Thesis Examination Committee has met on 31 March 2016 to conduct the final examination of Sariah binti Saalah on her thesis entitled "Synthesis and Characterisation of Jatropha Oil-Based Waterborne Polyurethane Dispersions" in accordance with the Universities and University Colleges Act 1971 and the Constitution of the Universiti Putra Malaysia [P.U.(A) 106] 15 March 1998. The Committee recommends that the student be awarded the Doctor of Philosophy.

Members of the Thesis Examination Committee were as follows:

Salmiaton binti Ali, PhD

Associate Professor
Faculty of Engineering
Universiti Putra Malaysia
(Chairman)

Suraya binti Abdul Rashid, PhD

Associate Professor
Faculty of Engineering
Universiti Putra Malaysia
(Internal Examiner)

Norhafizah bt Abdullah, PhD

HDA	1-6 Hexanediamine
HEMA	2-Hydroxyethyl methacrylate
H ₁₂ MDI	4-4 dicyclohexylmethane diisocyanate
IPDI	Isophrene (or isophorone) diisocyanate
IV	Iodine value
JO	Jatropha oil
JOL	Jatropha oil-based polyol
JPU	Jatropha oil-based waterborne polyurethane
MDI	Diphenylmethane diisocyanate
MFFT	Minimum film forming temperature
OOC	Oxirane oxygen content (%)
OOC _{th}	Theoretical oxirane oxygen content (%)
PU	Polyurethane

SEM	Scanning Electron Microscope
TEA	Triethylamine
TDI	Toluene diisocyanate
TGA	Thermogravimetric Analysis
ZP	Zeta potential (mV)
d_{50}	Average particle size (nm)
gram/eq	Gram per equivalent
M_c	Molecular weight between crosslink
M_n	Number average molecular weight (Dalton)
M_w	Weight average molecular weight (Dalton)
n	Flow index behavior
OH	Hydroxyl
R	Universal gas constant
Tan δ	Damping, ratio of E''/E'
T_g	Glass transition temperature ($^{\circ}\text{C}$)
σ	Tensile strength (MPa)
B	Titration of blank (mL)
ε	Elongation at break (5)
η	Viscosity (mPas)
η^*	Complex viscosity (mPas)
N	Normality
W	Weight (g)
S	Titration of the sample (mL)
f	Functionality
ω	Angular frequency (s^{-1})
ρ_2	Density of dry polymer
γ	Shear rate (s^{-1})
δ	Solubility parameter
v_1	Molar volume of solvent
v_e	Crosslinking density
ϕ_2	Volume fraction of polymer in the swollen network
χ_{12}	Polymer–solvent interaction parameter

CHAPTER 1

INTRODUCTION

1.1 Background of the study

Polyurethane (PU) is a versatile polymer which has been employed in a wide range of applications, such as coatings, adhesives, sealants, foams, elastomers, and others. With a proper selection of reactant, PU ranges from high performance elastomers to tough and rigid plastics can be easily fabricated (Lu & Larock, 2008). PU based coatings have an established place in the coatings industry due to the high level of quality such as outstanding chemical and corrosion resistance, excellent abrasion resistance, low temperature flexibility, high toughness, and a wide range of mechanical strength (Kong, et al., 2013; Melchioris et al., 2000). Basically, polyurethane backbone structures consist of a soft segment from polyol, and a hard segment from isocyanate. The hard segments govern the hardness, strength and toughness of the PU films, while the soft segments determine the flexibility and glass transition temperature. The versatile mechanical properties of PU arise from phase separation of the thermodynamically incompatible hard and soft segments, which arrange themselves in microdomains as a result of a hydrogen bonding bridge between the urethane groups (Kanda et al., 2008). The hydrogen bridge bond forms a stable physical network, ensuring the outstanding mechanical properties of the PU film, while the urethane groups helps to protect the polymer chain against solvents, acids, bases and other chemicals (Melchioris et al., 2000).

Traditional PU coatings have been diluted with an organic solvent that helps to carry the coatings from the applicator to the substrate. Organic solvents often contain volatile organic compounds (VOCs). The emission of VOCs during the formulation of coatings, inks, and paints has caused a wide variety of air quality problems (Nanda & Wicks, 2006). With enforcement of stringent regulations aimed at preventing pollution, such as the Clean Air Act, the application of solvent-borne coatings has been phased out and replaced with coatings free of VOCs such as waterborne coatings and ultraviolet (UV) curable coatings (100 % solid) (Athawale & Kulkarni, 2010; DeVito, 1999; Ristić et al., 2012). In Europe, waterborne technology has been accepted as it has become the largest volume of coatings particularly in terms of decorative coatings (Scrinzi et al., 2011). These products fulfil many of the requirements related to conventional solvent-borne coatings, e.g., low viscosity at a high molecular weight and good applicability (Cakić et al., 2013). The transition from solvent-borne to waterborne PU may lower the manufacturing costs associated with solvent cost, and reduce the health and fire risks (Garrison et al., 2014). It has been forecast that the global PU dispersion market will grow at a CAGR of 7.5 % in the years 2012 to 2018, with the market value estimated to be worth US \$ 1.18 billion by 2018 (Transparency Market Research, 2015b).

Waterborne polyurethane (PU) dispersion is a typical colloid system consisting of PU particles stabilised in a continuous water phase. In preparing a waterborne PU dispersion, ionomers which contain hydrophilic groups are incorporated into the side chain or the backbone of the polymer to enable dispersibility of the water-insoluble polyurethane. Anionic ionomers such as dimethylol propionic acid (DMPA) act as an emulsifier to provide dispersion stability for longer storage of the waterborne PU dispersion. Currently, most waterborne PU dispersions are derived from a petroleum based polyol which is non-renewable. As fossil resources become depleted, coupled with awareness of environmental issues related to non-biodegradable products, utilisation of more sustainable and environmentally friendly raw materials for fabrication of bio-based polymers is gaining increasing attention. Recently, the successful synthesis of waterborne PU dispersions from vegetable oil based polyol derived from soybean oil, castor oil, rapeseed oil and linseed oil has been reported (Chang & Lu, 2013; Lu & Larock, 2008; Ni et al., 2010). However, to the best of the knowledge of the authors, no research has been reported on the production of waterborne PU dispersions from non-edible jatropha oil. In Malaysia, jatropha has become one of the most important crops after palm oil and rubber, mainly planted for biodiesel production. BATC Development Berhad has been actively engaged in jatropha plantation and the bio-fuel industry since 2007. Up to 2011, about 600,000 acres of planted area, 3.3 million acres in landbanks and more than 300 nurseries and collection centres were reported in Malaysia (Bionas, 2011).

Jatropha oil (JO) which is extracted from the seeds of the jatropha fruit is a promising candidate for chemical purposes as it contains 78.9 % unsaturated fatty acids, mainly of oleic acid (43.1 %) and linoleic acid (34.4 %) (Sarin et al., 2007). This high degree of unsaturation provides a broad alternative for chemical modification to produce polymers with the desired properties. Furthermore, the utilisation of a non-edible jatropha oil will reduce the dependency on edible oils for chemical purposes (Rios et al., 2011). Previous research has revealed the potential usage of jatropha oil for production of various polymers with promising properties such as alkyd resin, PU coatings, PU adhesive and PU elastomer (Aung et al., 2014; Boruah et al., 2012; Harjono et al., 2012; Hazmi et al., 2013). In this research, an attempt is made to extend the potential of jatropha oil as a starting material for the production of a waterborne PU dispersion.

1.2 Problem statement

Malaysia is among the largest of the world's producers of palm oil. In the coating industry, successful utilisation of such oil has been reported to produce alkyd resin, epoxy palm oil, oleic acid acrylate resin and PU acrylate for wood coatings and overprint varnish applications (Rozman et al., 2013). Due to the low unsaturation in palm oil composition, production of a coating polymer from palm oil is more towards ultra-violet (UV) curable acrylate resin from palm oil derivatives such as oleic acid and palm oil monoglyceride (Rozman et al., 2013; Salleh et al., 2010; Wan Rosli et al., 2003). Realising the importance of reducing the dependency on edible oil for polymer fabrication, the non-edible jatropha oil is a new alternative. With almost 80 % unsaturated fatty acids, the double bond in the oil triglyceride structure could be directly functionalised to hydroxyl in polyol preparation.

Generally, vegetable oil with a high degree of C=C unsaturation will result in a high OH number polyol for crosslinking with isocyanate to produce polyurethane with good mechanical properties (Meier et al., 2007). The fatty acid composition of the starting vegetable oil and the polyol production method determine the properties of the final polyol such as OH number, molecular weight and rheology. As the polyol and isocyanate are the main ingredients in PU, the higher amount of polyol loading will increase the bio-based content. Typically, up to 60 wt.% bio-based content has been reported (Lu & Larock, 2008). Therefore, depending on the specific application, the properties of the PU could be tailored by varying the OH number of the polyol. The OH numbers will determine the appropriate amount of hard segment required for polymerisation. If a high bio-based PU is targeted, a low OH functionality polyol is selected, but the final film properties should be considered. The non-functional groups in the polyol may result in a tacky product which is undesirable for coating applications, but may be a characteristic of a pressure sensitive adhesive (Wool, 2005). On the other hand, the high functionality of some vegetable oil polyols may gel during polymerisation due to the higher crosslinking and therefore present potential difficulties in dispersing the PU prepolymers into water (Lu & Larock, 2008).

It is worth mentioning that the properties of the polyol also depend on the production method. As far as an industrially important two-step method, i.e. epoxidation followed by oxirane ring opening route, is concerned, various parameters should be controlled at each consecutive stage (Goud et al., 2010; Saurabh et al., 2011). Therefore, it is very important to conduct a systematic study of the effect of epoxidation parameters on the properties of jatropha oil-based polyol especially the OH numbers, as these will affect the properties of the waterborne polyurethane dispersions in the wet colloidal state as well as in the dry film state.

In general, the characteristics of the colloidal dispersions do not directly affect the mechanical properties of the resulting dry films. However, information on the colloidal stability and rheology of the dispersion is important with respect to storage and application. For example a low viscosity and molecular weight independent of the dispersed polymer is necessary for spray applications, but low zero shear rate viscosity is subject to sedimentation of the PU particles upon storage (Duffy, 2015; Kastner, 2001). A few factors have been reported to affect the stability of colloidal PU dispersions such as the degree of neutralisation and the stirring procedure. However, these are less important when compared to the ionic emulsifier content (Philipp & Eschig, 2012). The

ionic groups in the DMPA are reported to improve the mechanical properties, but tend to make the dispersion film more sensitive to water and chemicals (Bullermann et al., 2013). Therefore, the amount of DMPA should be controlled to be as low as possible yet sufficient to stabilise the PU particles upon storage. In addition, a balanced composition between soft segment (polyol) and the hard segment in the PU formulation is an important criterion to determine the mechanical properties of the polymers (Ni et al., 2010).

In this study, jatropha oil based waterborne PU dispersions will be prepared and characterised. The effect of polyol OH number, DMPA content and hard segment content with the stability of the wet jatropha oil-based polyurethane (JPU) dispersion and the physical, mechanical and thermal properties of the dry JPU films will be studied. On the other hand, the performance of the JPU dispersion as wood coatings will be evaluated. These properties will have an influence on the practical design of products as the PU dispersion can be used as a standalone coating or as a binder in wood and decorative coatings.

1.3 Objectives of the study

The main objective of this study is to investigate feasibility of producing jatropha oil-based waterborne polyurethane dispersions for coating applications. To achieve this objective, specific objectives have been identified:

- a. To investigate the effect of epoxidation conditions (molar ratio, time, temperature) on the properties of jatropha oil-based polyol.
- b. To investigate the effect of hard segment, hydroxyl number, and ionic emulsifier content on the colloidal stability and rheological properties of jatropha oil-based waterborne polyurethane dispersions.
- c. To relate the effect of hard segment, hydroxyl number and ionic emulsifier content on the physical, mechanical and thermal properties of jatropha oil-based waterborne polyurethane films.
- d. To evaluate the coating performance of jatropha oil-based waterborne polyurethane.

1.4 Scope of the study

The scope of the study can be expressed as follows.

- a. Preparation of jatropha oil based polyol by epoxidation and oxirane ring opening. Two series of epoxidised jatropha oil (EJO) to be obtained by varying the molar ratio formic acid to oil double bond from 0.4 to 1.0, at different temperatures, 50 °C and 60 °C. The third series to be produced at a fixed molar ratio of 0.6, temperature of 60 °C but with different reaction times. Only the third series will be selected for the oxirane ring opening step to produce jatropha oil-based polyols (JOL). The chemical and rheological properties of the EJO and JOL are to be investigated.
- b. Preparation of a jatropha oil based waterborne polyurethane (JPU) dispersion by the acetone method. Two group samples will be prepared: 1) a fixed molar

- ratio with varied hard segment (34-45 wt.%), and 2) a fixed hard segment at 45 wt.%.
- c. The colloidal stability of the JPU dispersion is to be evaluated by particle size analysis as well as rheological analysis.
 - d. The chemical, physical, mechanical and thermal properties of the JPU films are to be investigated and correlated with the composition of the JPU. Four samples will be selected for a coating application on wood substrate, and the performance of the coatings evaluated.

In this study, a waterborne JPU dispersion with properties that are comparable to a commercial PU dispersion is targeted. The specification of the commercial waterborne petro-based PU dispersion is provided in Table 1.1.

Table 1.1. Specification of commercial PU dispersion (Adapted from Kamsons Chemicals Pvt. Ltd. (n.d.))

Product name: Kamthane K-1432	
Type	Anionic, aliphatic
Appearance	Milky white
Total solids (% w/w)	38
pH	7.0-8.5
Viscosity (mPa.s)	30-90 (at 30 °C)
Elongation at break (%)	550
Konig hardness (s)	40

1.5 General overview of the thesis

The thesis is organised in five chapters. The first chapter provides the background of the research with an introduction to the waterborne polyurethane, followed by the problem statement, as well as the objectives and the scope of the present research.

In the second chapter, literature related to the modification of vegetable oil to polyol as well as the previous study on waterborne polyurethane is reviewed.

The third chapter focuses on the materials and methodology involved in the multistage preparation and characterisation of waterborne polyurethane from jatropha oil.

Chapter four covers the results and discussion of all experimental works. To facilitate the reading, the chapter is divided into four parts; 1) Production of jatropha oil-based polyol by epoxidation and oxirane ring opening, 2) Synthesis, stability and rheology of jatropha oil-based waterborne polyurethane dispersion, 3) Properties of jatropha oil-based waterborne polyurethane films, and 4) Performance of the waterborne polyurethane as wood coating.

Finally, the conclusions and recommendations are summarised in Chapter five.
