**MORPHOLOGICAL AND MOLECULAR CHANGES IN EMBRYO-
MATERNAL INTERACTIONS IN A RAT MODEL AT OPTIMAL AND
ELEVATED ENVIRONMENTAL TEMPERATURES**

By

HUDA YAHIA HAMID

March 2012

Chairman: Professor Md Zuki Bin Abu Bakar, PhD

Faculty: Veterinary Medicine

Early embryonic development, successful implantation, optimal fetal and placental development, and maintenance of a pregnancy are critically dependent on intact embryo-maternal interactions. Today, assisted reproductive technology (ART) is widely used to overcome some causes of infertility; however, the success rate remains low as a result of failures in communication between the transferred embryo and the endometrium. Failure in embryo-maternal communication is responsible for reproductive wastage, resulting in enormous economic loss. The mechanism that regulates embryo-maternal interaction has remained elusive and is not well understood. A better understanding of early embryo-maternal communication and the identification of the external factors that could interfere with embryo-maternal crosstalk will improve reproductive success in both humans and animals. The present study focuses on the maternal signals, which are responsible for two-thirds of pregnancy losses. Thus, the main objectives of this study were to define the

morphological and molecular changes that occur in the maternal tissue in response to the presence of the embryo and to determine the effects of elevated ambient temperatures on the morphological and molecular responses of maternal tissue to embryonic signals.

In the present study, implantation time was determined using blue dye injection (1% Chicago Sky Blue 6B). A radioimmunoassay (RIA) was used to estimate the plasma estradiol and progesterone levels during peri-implantation. Morphological changes in the rat oviduct and uterus during early pregnancy were examined under light and electron microscopes. Localization of transforming growth factor β 1 (TGF β 1), vascular endothelial growth factor (VEGF), basic fibroblast growth factor (bFGF), and their receptors TGF β R1, VEGFR2 (Flk-1), FGFR1 (Flg) in the oviduct and uterus was determined by immunohistochemistry. TGF β 1, VEGF, and bFGF gene expression levels in the rat uterus were examined by real-time quantitative RT-PCR.

The effects of elevated ambient temperatures on implantation time, number of implantation sites, plasma estradiol and progesterone concentrations, morphological changes, and the expression levels of TGF β 1, bFGF, and VEGF in the uterus during peri-implantation were also examined. Further, the effects of exposure to elevated temperatures at different stages of pregnancy on gestation length, litter size, neonatal deaths, sex ratio, birth weight, and offspring growth were also determined.

In the present study, implantation was initiated on day 5 and established by day 7 of pregnancy in the rats kept under optimal temperatures ($23\pm 1^\circ\text{C}$), while the rats exposed to elevated temperatures ($33\pm 2^\circ\text{C}$) exhibited delayed implantation and a

reduced number of implantation sites. Moreover, the exposure to elevated temperatures resulted in changes in the patterns of plasma progesterone and estradiol levels during peri-implantation.

Exposure to elevated ambient temperatures during early pregnancy resulted in prolonged gestation, reduced litter size, increased neonatal death, and a sex ratio biased toward males. Moreover, elevated temperatures adversely affected the birth weight and growth of offspring. Exposure to elevated ambient temperatures during the pre- and peri-implantation periods had stronger adverse effects on reproductive outcomes and offspring growth than post-implantation exposure.

Rats maintained under optimal conditions exhibited many morphological changes in the oviduct and uterus during early pregnancy. In the oviduct, the secretory cells were predominant during the first 4 days of pregnancy. On days 5 through 8 of pregnancy, however, the ciliated cells were predominant. In the uterus, extensive infiltration of leukocytes was observed in the endometrium during pre-implantation, whereas during implantation, the number of leukocytes decreased. Additionally, considerable changes occurred in the apical plasma membrane of the uterine epithelial cells. Such changes included changes in the length and density of the microvilli, flattening of the uterine epithelial cells, loss of the small secretory droplets seen near the epithelial cells, and the appearance of cytoplasmic protrusions (pinopods). The uterine luminal epithelial cells gradually lost their microvilli and became very flat. Pinopods were observed at the apical surface as early as day 2 of pregnancy. The incidence of pinopods increased gradually up to day 5 of pregnancy, when the pinopods became abundant and appeared in doughnut shaped.

In rats exposed to elevated ambient temperatures, there was a reduced incidence of pinopods on day 5 compared to the rats maintained under optimal temperatures. On day 6 of pregnancy, the rats exposed to elevated temperatures did not show flattening of the apical membrane.

Immunohistochemistry showed that TGF β 1, TGF β R1, VEGF, VEGFR2 (Flk-1), bFGF, and FGFR1 (Flg) were expressed in both the oviduct and uterus throughout the first 8 days of pregnancy; however, the distribution and intensity of immunostaining for each protein varied depending on the day of pregnancy. In the oviduct, high immunoreactivities of these growth factors and their receptors were observed while the embryo was present in the oviduct. In the uterus, TGF β 1, TGF β R1, VEGF, Flk-1, bFGF, and Flg were detected in the endometrium, i.e., in the epithelial and stromal cells.

Both immunohistochemical analysis and real time RT-qPCR revealed that TGF β 1, VEGF, and bFGF were found in the uterus at relatively lower levels during pre-implantation but that their expression levels increased dramatically during peri-implantation. Expression of TGF β 1 increased significantly on day 5 (8.72 ± 1.20 - fold increase versus day 0, $P < 0.001$) and day 5.5 (13.22 ± 1.80 - fold increase versus day 0, $P < 0.001$). A dramatic increase in TGF β 1 expression was detected on day 6 of pregnancy (46.38 ± 8.57 - fold increase versus day 0, $P < 0.0001$). Elevated expression of bFGF was observed immediately before implantation on day 5 (13.04 ± 1.79 - fold increase versus day 0, $P < 0.0001$), whereas VEGF showed elevated expression on day 5.5 (52.40 ± 6.50 - fold increase versus day 0, $P < 0.0001$).

The TGFβ1 mRNA levels in the uteri of rats exposed to elevated temperatures on days 5, 5.5, and 6 of pregnancy were significantly ($P < 0.01$) lower than the expression levels in the uteri of rats kept under optimal temperatures at the same stages of pregnancy. VEGF and bFGF expression in the uteri of rats exposed to elevated temperatures on days 5 and 5.5 were significantly ($P < 0.01$) lower than the expression levels in uteri of rats maintained under optimal temperatures at the same stages of pregnancy, while high expression levels were observed on day 6 of pregnancy.

In conclusion, implantation in rats was initiated on day 5 and established by day 7 of pregnancy. Elevated ambient temperatures can delay implantation and reduce the number of implantation sites. Elevated temperatures disturb the plasma estradiol and progesterone levels during peri-implantation. Elevated temperatures can also lead to prolonged gestation time, decreased litter size, neonatal death, and a sex ratio biased toward males. Additionally, exposure to elevated temperatures during early pregnancy has adverse effects on offspring growth. The exposure of pregnant rats to elevated temperatures during the pre- and peri-implantation stages has stronger adverse effects on reproductive performance than post-implantation exposure.

Morphological alterations in the apical plasma membrane indicate endometrial receptivity. The expression patterns of TGFβ1, VEGF and bFGF and their receptors in the oviduct indicate that these growth factors contribute to early embryonic development. High expression levels of TGFβ1, VEGF, and bFGF during peri-implantation suggest that these growth factors play roles in implantation in rats. Exposure of pregnant rats to elevated temperatures affects the responses of uterine tissue (i.e., both morphological and molecular responses) to embryonic signals,

leading to delay or failure of implantation. Overall, this study reveals that morphological alterations and growth factors (TGF β 1, VEGF, and bFGF) are involved in embryo-maternal interactions and that elevated environmental temperatures interfere with the embryo-maternal crosstalk during peri-implantation, leading to implantation delay/failure. These findings can help in the diagnosis and treatment of non-receptive endometria and abnormal embryo-maternal interactions.

Abstrak tesis yang dikemukakan kepada Senat Universiti Putra Malaysia sebagai memenuhi keperluan untuk ijazah Doktor Falsafah

**PERUBAHAN MORFOLOGI DAN MOLEKUL DALAM INTERAKSI
EMBRIO-IBU DALAM MODEL TIKUS PADA SUHU PERSEKITARAN
YANG OPTIMUM DAN YANG TINGGI**

Oleh

HUDA YAHIA HAMID

Mac 2012

Pengerusi: Profesor Md Zuki Bin Abu Bakar, PhD

Fakulti: Perubatan Veterinar

Pembangunan awal embrio, kejayaan implantasi, pembangunan optimum janin dan plasenta, dan penyelenggaraan bagi kehamilan amat bergantung kepada interaksi embrio-ibu yang utuh. Kegagalan dalam komunikasi embrio-ibu bertanggungjawab bagi pembaziran pembiakan, mengakibatkan kerugian ekonomi yang besar. Hari ini, teknologi pembiakan bantuan (ART) digunakan secara meluas untuk mengatasi beberapa penyebab kemandulan; bagaimanapun, kadar kejayaan masih rendah akibat kegagalan dalam komunikasi antara embrio yang dipindahkan dan endometrium. Mekanisme yang mengawal interaksi embrio-ibu masih sukar difahami dan tidak difahami dengan baik. Pemahaman yang lebih baik dalam komunikasi awal embrio-ibu dan mengenal pasti faktor-faktor luaran yang boleh mengganggu interaksi embrio-ibu akan meningkatkan kejayaan pembiakan dalam kedua-dua manusia dan haiwan. Kajian ini memberi tumpuan kepada isyarat ibu, yang bertanggungjawab bagi dua pertiga daripada kerugian kehamilan. Oleh itu, objektif utama kajian ini

adalah untuk mentakrifkan perubahan morfologi dan molekul yang berlaku dalam tisu ibu sebagai tindak balas kepada kehadiran embrio dan juga untuk menentukan kesan suhu tinggi persekitaran ke atas tindakbalas morfologi dan molekul tisu ibu kepada isyarat embrio.

Dalam kajian ini, masa implantasi telah ditentukan dengan menggunakan suntikan pewarna biru (1% Chicago Blue Sky 6B). Radioimmunocerakinan (RIA) telah digunakan untuk menganggarkan paras plasma estradiol dan progesteron semasa peri-implantasi. Perubahan morfologi dalam oviduct dan rahim tikus semasa awal kehamilan telah diperiksa di bawah mikroskop cahaya dan elektron. Penyetempatan faktor pertumbuhan pengubah $\beta 1$ (TGF $\beta 1$), faktor pertumbuhan vaskular endotelium (VEGF) yang, faktor pertumbuhan fibroblast asas (bFGF), dan reseptor mereka TGF $\beta R1$, VEGFR2 (Flk-1), FGFR1 (Flg) dalam oviduct dan uterus telah ditentukan oleh Immunohistokimia. TGF $\beta 1$, VEGF dan bFGF ungkapan tahap gen dalam rahim tikus telah diperiksa oleh masa sebenar kuantitatif RT-PCR.

Kesan suhu tinggi persekitaran ke atas masa implantasi, bilangan tapak implantasi, kepekatan estradiol dan progesteron plasma, perubahan morfologi, dan tahap ungkapan TGF $\beta 1$, bFGF, dan VEGF dalam rahim semasa peri-implantasi turut diperiksa. Di samping itu, kesan pendedahan kepada suhu tinggi di pelbagai peringkat kehamilan pada panjang kandungan, saiz kelahiran, kematian neonatal, nisbah jantina, berat lahir, dan pertumbuhan anak-anak juga ditentukan.

Dalam kajian ini, implantasi bermula pada hari ke 5 dan lengkap pada hari ke 7 kehamilan di dalam tikus yang disimpan di bawah suhu optimum ($23 \pm 1^\circ\text{C}$),

manakala tikus yang terdedah kepada suhu tinggi ($33 \pm 2^{\circ}\text{C}$) menunjukkan kelewatan implantasi dan bilangan yang berkurangan bagi tapak implantasi. Tambahan pula, pendedahan kepada suhu tinggi menyebabkan perubahan dalam corak progesteron plasma dan paras estradiol semasa peri-implantasi.

Pendedahan kepada suhu tinggi ambien pada awal kehamilan menyebabkan kehamilan yang panjang, mengurangkan saiz kelahiran, meningkatkan kematian neonatal dan nisbah jantina yang condong kepada lelaki. Selain itu, suhu tinggi menjejaskan berat kelahiran dan pertumbuhan anak-anak. Pendedahan kepada suhu tinggi ambien pada masa pra- dan peri-implantasi mempunyai kesan yang lebih teruk ke atas hasil-hasil pembiakan dan pertumbuhan anak daripada pendedahan selepas implantasi.

Tikus yang dikekalkan di bawah keadaan optimum menunjukkan banyak perubahan morfologi dalam oviduct dan uterus semasa awal kehamilan. Dalam oviduct, sel-sel pengeluaran adalah dominan dalam tempoh masa 4 hari pertama kehamilan. Pada hari ke 5 hingga 8 kehamilan, bagaimanapun, sel-sel bersilia adalah dominan. Dalam rahim, infiltrasi sel leukosit banyak diperhatikan dalam endometrium semasa pra-implantasi, manakala semasa implantasi, bilangan leukosit menurun. Selain itu, perubahan yang agak besar berlaku dalam membran plasma apeks sel-sel epitelium rahim. Perubahan tersebut termasuklah perubahan dalam panjang dan ketumpatan mikrovilus, kesamarataan sel-sel epitelium rahim, kehilangan pengeluar titisan-titisan kecil yang dilihat berhampiran sel-sel epitelium, dan keadaan unjuran cytoplasmic (pinopods). Sel-sel epitelium lumen rahim kehilangan mikrovilus secara beransur-ansur dan menjadi sangat rata. Pinopods diperhatikan di permukaan apikal seawal

hari ke 2 kehamilan. Kehadiran pinopods meningkat secara beransur-ansur sehingga hari ke 5 kehamilan, apabila pinopods menjadi banyak dan kelihatan dalam bentuk donat.

Dalam tikus yang terdedah kepada suhu ambien yang tinggi, pinopods berkurangan pada hari ke 5 berbanding dengan tikus yang disimpan di bawah suhu optimum. Pada hari ke 6 kehamilan, tikus-tikus yang terdedah kepada suhu tinggi tidak menunjukkan kesamarataan membran apikal.

Immunohistokimia menunjukkan TGF β 1, TGF β R1, VEGF, VEGFR2 (Flk-1), bFGF dan FGFR1 (Flg) terdapat dalam kedua-dua oviduct dan rahim sepanjang 8 hari pertama kehamilan, namun, pengedaran dan intensiti immunostaining bagi setiap protein berbeza bergantung kepada hari kehamilan. Dalam oviduct, immunoreactivities yang tinggi bagi faktor-faktor pertumbuhan dan reseptor diperhatikan semasa embrio hadir dalam oviduct itu. Dalam rahim, TGF β 1, TGF β R1, VEGF, Flk-1, bFGF dan Flg dikesan dalam endometrium, iaitu, dalam sel-sel epitelium dan stroma.

Kedua-dua analisis immunohistochemical dan masa nyata RT-qPCR mendedahkan bahawa TGF β 1, VEGF dan bFGF ditemui dalam rahim pada paras yang agak rendah semasa pra-implantasi tetapi tahap ungkapan mereka meningkat secara mendadak semasa peri-implantasi. Ekspresi TGF β 1 meningkat dengan ketara pada hari ke 5 (8.72 ± 1.2 kali ganda berbanding hari 0, $P < 0.001$) dan hari ke 5.5 (13.22 ± 1.8 kali ganda berbanding hari 0, $P < 0.001$). Peningkatan dramatik dalam TGF β 1 ungkapan dikesan pada hari ke 6 kehamilan ($46.38 \pm .8.57$ kali ganda berbanding

hari 0, $P < 0.0001$). Ungkapan tinggi bFGF diperhatikan sebaik sebelum penanaman pada hari ke 5 (13.04 ± 1.79 - kali ganda berbanding hari 0, $P < 0.0001$), manakala VEGF menunjukkan ungkapan tinggi pada hari ke 5.5 (52.4 ± 6.5 kali ganda berbanding hari 0, $P < 0.0001$).

Tahap TGF β 1 mRNA dalam rahim tikus yang terdedah kepada suhu tinggi pada hari ke 5, 5.5 dan 6 kehamilan adalah lebih rendah ($P < 0.01$) daripada tahap ungkapan dalam rahim tikus yang disimpan di bawah suhu optimum di peringkat kehamilan yang sama. Ungkapan VEGF dan bFGF dalam rahim tikus yang terdedah kepada suhu tinggi pada hari ke 5 dan 5.5 adalah lebih rendah ($P < 0.01$) daripada tahap ungkapan dalam rahim tikus yang diselenggarakan di bawah suhu optimum di peringkat kehamilan yang sama, manakala tahap ungkapan tinggi diperhatikan pada hari ke 6 kehamilan.

Kesimpulannya, implantasi dalam tikus telah dimulakan pada hari ke 5 dan dilengkapkan pada hari ke 7 kehamilan. Suhu persekitaran yang tinggi boleh melambatkan implantasi dan mengurangkan bilangan tapak implantasi. Suhu tinggi mengganggu paras estradiol dan progesteron plasma semasa peri-implantasi. Suhu bertingkat juga boleh membawa kepada masa matang yang panjang, penurunan saiz kelahiran, kematian neonatal, dan nisbah jantina yang condong kepada lelaki. Selain itu, pendedahan kepada suhu tinggi semasa awal kehamilan mempunyai kesan buruk ke atas pertumbuhan anak-anak. Pendedahan tikus yang mengandung kepada suhu tinggi semasa peringkat pra-dan peri-implantasi mempunyai kesan buruk yang kuat terhadap prestasi pembiakan daripada pendedahan selepas implantasi. Perubahan morfologi dalam membran apikal plasma menunjukkan kesediaan menerima oleh

endometrium. Corak ungkapan TGF β 1, VEGF, dan bFGF dan reseptor mereka dalam oviduct menunjukkan bahawa faktor-faktor pertumbuhan menyumbang kepada pembangunan embrio awal. Tahap ungkapan yang tinggi TGF β 1, VEGF, dan bFGF semasa peri-implantasi mencadangkan bahawa faktor-faktor pertumbuhan memainkan peranan dalam implantasi dalam tikus. Pendedahan tikus yang mengandung kepada suhu tinggi memberi kesan kepada tindak balas tisu rahim (iaitu, jawapan kedua-dua morfologi dan molekul) isyarat embrio, yang membawa kepada kelewatan atau kegagalan penanaman. Oleh itu, perubahan morfologi dan faktor pertumbuhan (TGF β 1, VEGF, dan bFGF) terbabit dalam komunikasi awal embrio-ibu. Penemuan ini boleh membantu dalam diagnosis dan rawatan kes-kes seperti non-receptive endometria dan ketidaknormalan interaksi embrio-ibu.

ACKNOWLEDGEMENTS

First of all, my utmost thanks, praise and gratitude to the Almighty Allah S. W. T. who has given me the strength to complete this work (Alhamdulillah) and my salawat and salam to His prophet Muhammad (S.A.W.).

I would like to express my sincere thanks and gratitude to Prof. Dr. Md Zuki Abu Bakar for his helpful supervision, suggestions and continuous support throughout this work. I wish to express my thanks and appreciation also to the members of the supervisory committee, Prof. Dr. Abd. Wahid Haron, Prof. Dr. Noordin Mohamed Mustapha, and Assoc. Prof. Dr. Goh Yong Meng for their advice and guidance.

I would like to express my deepest gratitude and sincere appreciation to Prof. Dr. Tengku Azmi Tengku Ibrahim for his advice and invaluable help.

Deepest thanks and gratitude are due to Prof. Dr. Muddathir D. Tingari, Department of Anatomy, University of Khartoum for his continuous support and encouragement.

Profound thanks go to the University of Khartoum, Sudan for providing me the financial support during this study. I am also grateful to the Fundamental Research Grant Scheme, Malaysia for financing this work.

My appreciation is due to Dr. Tan Sheau Wei from Molecular Biomedicine Lab-Institute of Bioscience for her cooperation and valuable help in RT-qPCR.

I am indebted to Mr. Zainuddin Ibrahim, Mr. Ismail Shaari and Mr. Kumar Rajagopal for their generous help and cooperation in providing all the facilities needed for the experimental animals. My thanks are extended to Mr. Rafiuz Zaman Haroun, Mrs. Faridah Akmal Ismail (Microscopy Unit, Institute of Bioscience), Ms. Kuna (Histology Lab.), Mr. Siva Soorian Ramasamy (Anatomy Lab.), Mrs. Latifah Mohd Hanan and Mrs. Jamilah Jahari (Histopathology Lab.) for their help and providing the equipments needed during the laboratory work.

Sincere thanks to my brothers and sister for their encouragement and moral support. Special thanks and gratitude are extended to my husband Dr. Adil Hassan and my daughters Asgad and Shahd for their tremendous patience and support.

Last but not the least, thanks are also extended to all my colleagues especially Haytham Hajo, Nurhusien Yimer, Alireza Rezaeizadeh and Elhareth Yahya and to those who contributed in any way but not mentioned here.

I certify that a Thesis Examination Committee has met on 6 March 2012 to conduct the final examination of Huda Yahia Hamid Fadlalla on her thesis entitled "Morphological and Molecular Changes in Embryo-Maternal Interactions in a Rat Model at Optimal and Elevated Environmental Temperatures" in accordance with the Universities and University College Act 1971 and the Constitution of the Universiti Putra Malaysia [P.U.(A) 106] 15 March 1998. The committee recommends that the student be awarded the Doctor of Philosophy.

Members of the Thesis Examination Committee were as follows:

Mohamed Ariff bin Omar, PhD

Professor
Faculty of Veterinary Medicine
Universiti Putra Malaysia
(Chairman)

Mohd Hair bin Bejo, PhD

Professor

2.2	Schematic illustration of VEGF receptors and their interaction with the growth factors	34
2.3	Domain structure of generic FGF and FGFR proteins. A: Structure of a generic FGF protein containing a signal sequence and the conserved core region that contains receptor- and HSPG-binding sites. B: The main structural features of FGFRs including Ig domains, acidic box, heparin-binding domain, CAM-homology domain (CHD), transmembrane domain, and a split tyrosine kinase domain are illustrated with respective functions	36
3.1	Vaginal smear on day 1 of pregnancy. Note the spermatozoa, the large number of leukocytes (arrows), and the cornified cells (C). Giemsa stain. Scale bar 200 μ m	46
3.2	Uterus of rat maintained at $23\pm 1^{\circ}\text{C}$ on the afternoon of day 5 of pregnancy	51
3.3	The implantation sites on the afternoon of day 6 of pregnancy. A) Uterus of rat maintained under optimal temperatures. B) Uterus of rat exposed to elevated temperatures. The blue bands indicate the implantation sites (arrows). Note the blue bands in exposed rat uterus are thin, fewer in number, and pale compared with those in non-exposed rat uterus	52
3.4	The number of implantation sites of rats maintained under optimal temperatures ($23\pm 1^{\circ}\text{C}$) and those exposed to elevated temperatures ($33\pm 2^{\circ}\text{C}$) on days 6 and 8 of pregnancy. The bars represent the mean \pm SEM. Levels of significant are shown by asterisks (** $P < 0.01$; **** $P < 0.0001$)	53
3.5	Progesterone concentrations (ng/ml) in rats kept under optimal temperatures ($23\pm 1^{\circ}\text{C}$) and those exposed to elevated temperatures ($33\pm 2^{\circ}\text{C}$) on day 5 (afternoon and evening) and day 6 of pregnancy. The bars represent the mean \pm SEM. A significant difference is indicated by an asterisk ($P < 0.05$)	56

3.6	Estradiol concentrations (pg/ml) in rats kept under optimal temperatures ($23\pm 1^{\circ}\text{C}$) and those exposed to elevated temperatures ($33\pm 2^{\circ}\text{C}$) on day 5 (afternoon and evening) and day 6 of pregnancy. The bars represent the mean \pm SEM. A significant difference is indicated by an asterisk ($P < 0.05$)	56
3.7	The P4:E2 ratio in the group kept under optimal temperatures ($23\pm 1^{\circ}\text{C}$) and in the group exposed to elevated temperatures ($33\pm 2^{\circ}\text{C}$) on day 5 (afternoon and evening) and day 6 of pregnancy	57
4.1	Schematic illustration of pregnancy period and time of exposure to elevated temperatures in the four groups	66
4.2	The gestation lengths of the control group (group 1) and groups exposed to elevated temperatures. The bars represent the mean \pm SEM. Data labeled with different letters are significantly different at $P < 0.001$	67
4.3	The litter sizes produced by the females of the control group (group 1) and groups exposed to elevated temperatures. The bars represent the mean \pm SEM. Data labeled with different letters are significantly different at $P < 0.05$	69
4.4	The percentages of neonatal deaths in the control group (group 1) and in the three groups exposed to elevated temperatures	69
4.5	The percentages of males produced in the control group (group 1) and groups exposed to elevated temperatures. Data represent the mean \pm SEM. Data labeled with different letters are significantly different at $P < 0.01$	70
4.6	The growth curves for the male (A) and female (B) pups of the control group and the three groups exposed to elevated temperatures from birth until weaning. Data represent the mean \pm SEM	72
5.1	Rat oviduct under dissecting microscope. I, infundibulum; A, ampulla; S, isthmus	85
5.2	The uterus on day 5 of pregnancy. Note the embryonic sites (arrows)	87
5.3	Embryonic sites in the uterus. Note the embryonic sites appear as small balls or beads. A) After 7 days of pregnancy. B) After 8 days of pregnancy	88
5.4	Ampulla and isthmus of the oviduct. The mucosa is highly folded in the ampulla (A), while in the isthmus (S) it has fewer folds. H&E stain. Scale bar 500 μm	89
5.5	Interstitial part of the oviduct. A) On day 1 of pregnancy, lumen of the interstitial part (N) is closed. B) On day 2 of pregnancy, the	90

- lumen of the interstitial part is opened. H&E. Scale bar 500 μm
- 5.6 The isthmus on day 1 of pregnancy. The lumen contains fragments of spermatozoa. The heads of spermatozoa (arrows) can be seen in contact with the epithelial cells. H&E stain. Scale bar 50 μm 91
- 5.7 Uterine stroma. The stromal cells are abundant, occupying the spaces of the fibrous mesh. Note, lymphocytes (open arrows), eosinophil (arrowhead), and neutrophil (arrow). H&E stain. Scale bar 20 μm 92
- 5.8 The myometrium is composed of inner circular layer (C) and outer longitudinal layer (L) of smooth muscles. Note the vascular layer (V), a layer of blood vessels found between the two layers of smooth muscle. Perimetrium (arrows); S, stroma. Masson's Trichrome stain. x100 93
- 5.9 The uterus on day 1 of pregnancy. A) The uterine lumen contains an accumulation of spermatozoa fragments (F). B) The endometrium and myometrium showing extensive infiltration of leukocytes. Note the accumulation of neutrophils near the blood vessel (N), within the smooth muscles of the myometrium (arrows), and in the vascular layer (open arrow). C) Insert, high magnification (x400) of the demarcated area, shows numerous neutrophils in the stroma. H&E stain. Scale bar 100 μm for A and 200 μm for B 95
- 5.10 The endometrial-myometrial junction on day 4 of pregnancy showing extensive infiltration of leukocytes. Note the eosinophils (arrows) are abundant. S, stroma; M, myometrium. H&E stain. Scale bar 50 μm 96
- 5.11 The uterus on day 5 of pregnancy. Note the intraepithelial lymphocytes (open arrow) and the lymphocytes in the subepithelial stroma (arrows). Arrowhead points to the apical protrusion (pinopod). H&E stain. Scale bar 50 μm 97
- 5.12 The uterus on day 5 of pregnancy. A) The endometrium showing damaged uterine glands. Note the glandular epithelial necrosis and totally regressed glands (R). Scale bar 100 μm . B) The stroma near the damaged glands. Note the macrophage contains phagocytized materials (arrows). H&E stain. Scale bar 20 μm 98
- 5.13 Cross section of the uterus at implantation site on day 7 of pregnancy shows complete implantation. em, embryo. x40. B) Insert, shows that the epithelium at the implantation site is cuboidal or flattened cells (arrowheads). H&E stain. x200 99
- 5.14 EM micrographs of the oviduct on day 1 of pregnancy. A) SEM micrograph. Note the small vesicles can be seen in contact with the microvilli as well as cilia (arrows). x4000. B) TEM micrograph. 102

- Secretory cells are predominant. Note the dense apical granules (G) and the well-developed microvilli (M). x3550
- 5.15 EM micrographs of the oviduct on day 6 of pregnancy. A) The ciliated cells are predominant. x2000. Note the large vesicles (*) at the apical surfaces of the secretory cells (insert). x4000. B) A secretory cell has extensive RER. N, nucleus. x15000 102
- 5.16 TEM micrographs of the oviduct on day 7 of pregnancy. A) The ciliated cells are predominant. Note the well-developed cilia. x3550. B) High magnification of the demarcated area in A. x16500. C) Secretory cells possess poorly developed microvilli (MV). Vesicle (V) is seen blebbing from the cell surface. x10000 103
- 5.17 SEM micrograph of the oviduct on day 8 of pregnancy shows dense and well-developed cilia. x15000 104
- 5.18 TEM micrographs of the oviduct show intercellular spaces on day 2 (A) and day 8 of pregnancy (B). The intercellular spaces on day 8 are larger than those observed on day 2 of pregnancy. The microvilli are protruding into the intercellular space. Note the plasma membranes (arrows) of two secretory cells. x50000 for A and x40000 for B 104
- 5.19 SEM of the uterine luminal surface. A) The uterine luminal surface on day 1 of pregnancy is very folded. x25. Note the spermatozoa are found in the groove between the folds (insert). x4000. B) Epithelial cells on day 1 of pregnancy have dense microvilli. Note the small secretions. x4000. C) Epithelial cells on day 2 of pregnancy have sparse to medium density microvilli. Note the developing pinopods on some non-adjacent cells. x2000. D) Many well-developed pinopods are found on the luminal surface on day 3 of pregnancy. x2000. E) Uterine luminal surface on day 5 of pregnancy showing many pinopods (arrows). x2000. Note the pinopod appears in a doughnut shape (insert). x8000 107
- 5.20 SEM of the epithelial cells of pregnant rat uterus at implantation sites. A) The epithelial cells on day 6 of pregnancy lack microvilli. x8000. B) The epithelial cells on day 7 of pregnancy have sparse microvilli. x10000. C) The epithelial cells on day 8 of pregnancy have dense microvilli. Note the secretion droplets (arrowheads) and cell borders (arrows). x8000 108
- 5.21 TEM of the uterine luminal epithelial cells on days 1 and 3 of pregnancy. A) Epithelial cells on day 1 of pregnancy have regular dense microvilli (MV). Note the apical electron dense granules (white arrows). x15000. B) The microvilli are short and irregular on day 3. Many vacuoles (V) are found near the luminal surface. Note the pinopods (P) contain vacuoles. x16500 112

- 5.22 TEM of the uterine luminal epithelial cells on days 6 and 7 of pregnancy. A) The microvilli have disappeared on day 6. Note the flat surface (arrowheads) and small vacuoles (yellow arrows) in the apical part of the cell. x6000. B) Some cells showing irregular projections at the apical membrane on day 6 (arrows). x4600. C) High magnification of demarcated area in B. The epithelial cell contains mitochondria (M) lack well-defined cristae, numerous lysosomes (L), and large fat droplets (F). N, Nucleus. x16500. D) Uterine luminal epithelial cells on day 7 of pregnancy showing irregular microvilli returning to the apical membrane. Note some mitochondria (M) have defined cristae. x21500 113
- 5.23 The uterus of rat exposed to elevated temperatures in the evening of day 5 of pregnancy. Note the dilation at the upper part of the uterus (arrows) 114
- 5.24 The uterus of rat exposed to elevated temperatures on day 6 of pregnancy. Note the edematous stroma. H&E stain. Scale bar 200 μm 115
- 5.25 SEM of the uterine luminal surface of rat exposed to elevated temperatures on day 5 of pregnancy showing fewer pinopods (arrows) than those observed in non-exposed rat uterus at the same stage of pregnancy (compare with Fig. 5.19E). x4000 117
- 5.26 SEM of the uterine luminal surface of rat exposed to elevated temperatures on day 6 of pregnancy. Note, cells lacking microvilli (*) are fewer than those observed in non-exposed rat uterus at the same stage of pregnancy (compare with Fig. 5.20A). x8000 117
- 6.1 Immunolocalization of TGF β 1 in rat oviduct (ampulla). Note the reaction (brown color) at the apical surface of the epithelial cells. Scale bar 200 μm 137
- 6.2 Distribution of TGF β 1 in rat endometrium during early pregnancy. TGF β 1 is found in the epithelium (arrows) and stroma (S). A) TGF β 1 immunoreactivity on day 2 of pregnancy. Note the intensity of reaction. B) The endometrium on day 5 of pregnancy showing increased TGF β 1 immunoreactivity. C) The endometrium on day 6 of pregnancy. Note the strong TGF β 1 immunoreactivity in the stromal cells. Scale bar 100 μm 139
- 6.3 Immunoreactivity of TGF β 1 in the endometrium of heat-exposed rat on day 6 of pregnancy. The immunostaining is less intense than that observed in the non-exposed rat endometrium at the same stage of pregnancy, especially in the stroma (compare with Fig. 6.2C). Scale bar 100 μm 140

- 6.4 Immunoreactivity of TGF β R1 in rat oviduct. A) Infundibulum. B) Ampulla. C) Isthmus. Note the immunostaining in muscles (arrows). Scale bar 200 μ m for A and C, and 100 μ m for B 142
- 6.5 Immunoreactivity of TGF β R1 in the endometrium during early pregnancy. A) The endometrium on day 1 of pregnancy showing TGF β R1 immunostaining in the epithelium and stroma. B) The stroma on day 1, under high magnification. Note the eosinophil (arrow), neutrophil (open arrow), and plasma cell (double arrows). C) The endometrium on day 5 of pregnancy showing decline in TGF β R1 immunoreactivity. Note the immunostaining is concentrated in the epithelial cell membranes. D) The endometrium on day 6 of pregnancy showing increased TGF β R1 immunoreactivity. E) The endometrium on day 7 of pregnancy. Note the homogeneous distribution of TGF β R1 immunostaining in the cytoplasm of the epithelial and decidual cells. Scale bar 100 μ m for A, C, D; 20 μ m for B; 50 μ m for E 145
- 6.6 Immunolocalization of VEGF in rat oviduct. VEGF immunostaining is seen in the epithelial cells, with more intense reaction in the supranuclear cytoplasm. Note VEGF immunostaining in the smooth muscle cells (arrows). Scale bar 200 μ m 146
- 6.7 Distribution of VEGF in the endometrium during early pregnancy. A) On day 1 of pregnancy, VEGF immunostaining is seen in some epithelial and stromal cells. B) On day 2, the immunostaining is seen mainly in the epithelium. C) On day 4, the immunoreactivity declined. Note the reaction is mainly concentrated in the supranuclear region of the epithelial cell. D) The endometrium on day 5.5 of pregnancy. Note the strong immunoreactivity in the epithelial and stromal cells. E) An implantation site on day 8 showing strong VEGF immunoreactivity in the epithelial and decidual cells (D). Scale bar 100 μ m for A, B, C, E and 50 μ m for D 149
- 6.8 Immunoreactivity of VEGF in the uterus of heat-exposed rat on day 5.5 of pregnancy. The endometrium showing less intense VEGF immunoreactivity than that observed in non-exposed rat endometrium at the same stage of pregnancy (compare with Fig. 6.7D). Scale bar 50 μ m 150
- 6.9 Distribution of Flk-1 in rat uterus on day 1 of pregnancy. Note the Flk-1 immunostaining in the luminal and glandular epithelial cells, endothelial cells, and in the smooth muscles of the myometrium. Scale bar 200 μ m 154
- 6.10 Immunoreactivity of Flk-1 in the endometrium on day 6 of pregnancy. Note Flk-1 immunoreactivity in the epithelial cells, high reactivity at the apical surface (arrows). Strong Flk-1 immunoreactivity is seen in the decidual cells (D). Scale bar 200 μ m 154

- 6.11 Localization of bFGF in rat oviduct (isthmus). Note bFGF immunostaining at the apical membranes of epithelial cells lining the folds (arrows), while in the basal cells (arrowheads), bFGF immunostaining is seen in the cytoplasm. Scale bar 100 μ m 155
- 6.12 Immunoreactivity of bFGF in the endometrium during early pregnancy. A) On day 4 of pregnancy, bFGF immunostaining is concentrated at the apical surfaces of the epithelial cells. B) The endometrium on day 5 of pregnancy showing strong bFGF immunoreactivity in the epithelial, endothelial, and stromal cells. C) On day 6 of pregnancy, bFGF immunoreactivity declined compared with day 5. Note the immunostaining in the apical part of the epithelial cells and in pinopods (arrows). Scale bar 100 μ m for A, B and 50 μ m for C 158
- 6.13 Immunoreactivity of bFGF in the uterus of rat exposed to elevated temperatures. A) The endometrium on day 5 of pregnancy. B) The endometrium on day 6 of pregnancy. The endometrium on day 5 showing less intense bFGF immunoreactivity than that observed on day 6 (compare with non-exposed rat uterus in Figs. 6.12B and 6.12C). Scale bar 100 μ m 160
- 6.14 Immunoreactivity of Flg in the endometrium. A) Flg immunoreactivity on day 4 of pregnancy. B) The Flg immunoreactivity on day 8 of pregnancy. Compare the immunostaining in the epithelium during pre-implantation (A) with post-implantation (B). Note the strong Flg immunoreactivity in the decidual cells (D). Scale bar 100 μ m 164
- 6.15 The expression levels of TGF β 1 gene in rat uterus during pre- and peri-implantation. TGF β 1 mRNA levels were normalized to 18S rRNAs and expressed in fold changes relative to a corresponding non-pregnant sample (day 0). The bars represent the mean \pm SD. Data labeled with different letters are significantly different from each other ($P < 0.05$) 169
- 6.16 The effects of elevated temperatures on TGF β 1 gene expression levels in the uterus during peri-implantation. TGF β 1 mRNA levels were normalized to 18S rRNAs and expressed in fold changes relative to a 5 days pregnant non-exposed rat uterus sample. The bars represent the mean \pm SD. A significant difference between the uteri of heat exposed and non-exposed rats at the same day of pregnancy is indicated by asterisks ($P < 0.01$) 170
- 6.17 The expression levels of VEGF gene in rat uterus during pre- and peri-implantation. VEGF mRNA levels were normalized to 18S rRNAs and expressed in fold changes relative to a corresponding non-pregnant sample (day 0). The bars represent the mean \pm SD. Data labeled with different letters are significantly different from each other ($P < 0.05$) 171

- 6.18 The effects of elevated temperatures on VEGF gene expression levels in the uterus during peri-implantation. VEGF mRNA levels were normalized to 18S rRNAs and expressed in fold changes relative to a 5 days pregnant non-exposed rat uterus sample. The bars represent the mean±SD. A significant difference between the uteri of heat exposed and non-exposed rats at the same day of pregnancy is indicated by asterisks ($P < 0.01$) 172
- 6.19 The expression levels of bFGF gene in rat uterus during pre- and peri-implantation. bFGF mRNA levels were normalized to 18S rRNAs and expressed in fold changes relative to a corresponding non-pregnant sample (day 0). The bars represent the mean±SD. Data labeled with different letters are significantly different from each other ($P < 0.05$) 173
- 6.20 The effects of elevated temperatures on bFGF gene expression levels in the uterus during peri-implantation. bFGF mRNA levels were normalized to 18S rRNAs and expressed in fold changes relative to a 5 days pregnant non-exposed rat uterus sample. The bars represent the mean±SD. A significant difference between the uteri of heat exposed and non-exposed rats at the same day of pregnancy is indicated by asterisks ($P < 0.01$) 174

LIST OF ABBREVIATIONS

μg	microgram
μM	micromolar
μl	microlitre
μm	micron
bFGF	basic fibroblast growth factor
C	celcius
cm^3	cubic centimeter
C_T	cycle threshold
DNA	deoxyribonucleic acid
FGFR1/Flg	fibroblast growth factor receptor 1
Flk1	fetal liver kinase-1
g	gram
h	hour
H&E	haematoxylin and eosin
IS	implantation sites
M	molar
min	minutes
mg	milligram
ml	milliliter
mm^3	cubic millimeter
mRNA	messenger ribonucleic acid
ng	nanogram
nm	nanomolar

OD	optical density
PBS	phosphate buffer saline
PCR	polymerase chain reaction
pg	picogram
RER	rough endoplasmic reticulum
RNA	ribonucleic acid
RT-qPCR	real time quantitative polymerase chain reaction
SEM	scanning electron microscope
TEM	transmission electron microscope
TGF β	transforming growth factor beta
TGF β R1	transforming growth factor beta receptor 1
VEGF	vascular endothelial growth factor

CHAPTER ONE

INTRODUCTION

Early embryonic development, successful implantation, optimal fetal and placental development, and maintenance of a pregnancy are critically dependent on intact embryo-maternal interactions. The embryo-maternal dialogue starts immediately after fertilization and is exerted through both local and systemic signaling (Barnea, 2001). The presence of a biochemical network of embryo-maternal communication implies that various secreted molecules constitute a signal-response mechanism. This mechanism is crucial for the process of embryo implantation in mammals (Cocchiara *et al.*, 1996).

Communication between the embryo and mother and their reciprocal effects on each other are not fully understood, and thus constitute an exciting and unsolved problem in reproductive medicine (Simon *et al.*, 2001). Problems in the signaling mechanisms play a crucial role in early embryonic mortality since a high rate of embryonic mortality occurs during early pregnancy (Goff, 2002).

In farm animals, one of the most important problems in reproduction and breeding is early embryonic death, which has a substantial economic impact (Wolf *et al.*, 2003).

In cattle, for instance, 40% of total embryonic losses occur during early pregnancy; i.e. from day 8 to 17 of pregnancy (Humbolt, 2001; Thatcher *et al.*, 2001). Early embryonic loss is considered a principal obstacle to the reproductive success in all

domestic animals (Johnson *et al.*, 2003), as 25% of successful fertilizations do not result in viable fetuses (Roberts *et al.*, 1984).

In humans, early loss of pregnancy is a significant clinical problem. Although the human population is growing rapidly and is projected to reach nine billion by 2050, 15% of married couples worldwide have no children and 25% of them experience unexplained infertility (Cahill and Wardle, 2002; Wang and Dey, 2006). Currently, assisted reproductive technology (ART), such as *in vitro* fertilization and embryo transfer (IVF-ET), is widely used to overcome some causes of infertility, such as tubal scarring and male factors. Nevertheless, the rate of successful pregnancies is only 30% (Wang and Dey, 2006), and subsequent delivery rates are only 10-30% (Adamson *et al.*, 2006). The low success rate of ART is due to implantation failure, which occurs when the embryo is transferred to a non-receptive uterus; such failures occur despite excellent blastocyst quality, indicating the pivotal role of the endometrium in implantation.

Non-receptive endometria are responsible for about two-thirds of implantation failures, while the embryos are responsible for only one-third of failures (Simon *et al.*, 1998; Ledee-Bataille *et al.*, 2002). Uterine receptivity may be affected by internal as well as external factors.

The maternal environments during pre- and peri-implantation are thought to play a major role in the success of pregnancy, offspring viability and offspring health; most inherited diseases manifest at these early stages of pregnancy.

The definite mechanism that regulates the embryo-maternal dialogue until now is elusive and is not well understood. A better understanding of early embryo-maternal communication, and the external factors that could interfere with it, will help to increase the pregnancy rate by improving embryo transfer process, avoiding embryonic losses, and assisting in the diagnosis and treatment of non-receptive endometrium. Knowledge of the cells and molecules that are involved in embryo-maternal crosstalk, particularly during peri-implantation period, could help to solve two contrasting global problems by alleviating female infertility as well as by helping to develop novel contraceptives.

Identifying reliable markers of uterine receptivity will lessen the need to transfer multiple embryos to increase the success rate in *in vitro* fertilization and embryo transfer programs and therefore avoid the complications of multiple pregnancies. Not only is early maternal-embryonic interaction important for successful pregnancy, but it could also exert a significant influence on adult life in the future (e.g. body weight, diseases and likely behavior).

The current study focused on the maternal signals, which is responsible for two-thirds of the pregnancy failures. Particular attention was paid to the morphology of the oviduct and uterus during the presence of the embryo in these organs, and to the expression of transforming growth factor (TGF β 1), vascular endothelial growth factor (VEGF), and basic fibroblast growth factor (bFGF) in the maternal tissue during pre and peri-implantation period.

Perrier d'Hauterive *et al.* (2005) reported that TGF β 1 enhances the production of leukaemia inhibitory factor (a pro-implantation cytokine) from the endometrium. Moreover, over expression of Lefty (a TGF β 1 antagonist) in the mouse uterus reduces the number of implantation sites (Tang *et al.*, 2005). VEGF and basic FGF are implicated in angiogenesis, i.e., an essential process in the reproductive cycle (Friesel *et al.*, 1989; Bates, 2010). Thus, these growth factors seem to have pivotal roles during pregnancy. It would be significant to determine the expression patterns of these growth factors during pre-, peri- and post- implantation. Knowledge of these expression patterns will help in the diagnosis and treatment of such cases of infertility and also in the prevention and treatment of early pregnancy disorders.

Heat stress has a major influence on fertility and significantly reduces the reproductive and productive efficiency of farm animals (Jordan, 2003; Rensis and Scaramuzzi, 2003; Bloemhof *et al.*, 2008; Kornmatitsuk *et al.*, 2008; Udompraset and Williamson 1987). Several experimental studies in mice have shown that heat exposure for 12 h soon after mating compromises embryonic development, due to the effects of heat on the oviduct rather than on the embryo (Ozawa *et al.*, 2002; Ozawa *et al.*, 2003; Matsuzuka *et al.*, 2005; Sakamoto *et al.*, 2008). As implantation is the most sensitive process in pregnancy, the effects of exposure to elevated ambient temperatures on the maternal responses to implantation should be investigated.

This study aimed to generate more meaningful information about the maternal signals during pre-, peri- and post-implantation periods. The secondary focus is the effect of elevated ambient temperatures (an external factor) on implantation,

maternal signals during peri-implantation, reproductive outcomes and offspring growth.

Thus, the hypothesis of this study was that the morphology of the oviduct and endometrium and the expression of local growth factors change in response to embryonic signals and, additionally, the environmental conditions affect embryo-maternal crosstalk.

The main objective of this study was to define the morphological and molecular changes that occur in the maternal tissue in response to the presence of the embryo.

The specific objectives were:

- i. to determine the time of implantation in rats and the concentrations of plasma progesterone and estradiol during peri-implantation,
- ii. to define the morphological changes in the oviduct and uterus during early pregnancy,
- iii. to determine the distribution and expression pattern of the growth factors and their receptors in the oviduct and uterus during early pregnancy,
- iv. to determine the effects of elevated ambient temperatures on implantation, concentrations of plasma progesterone and estradiol, morphological changes and growth factor expressions during peri-implantation, as well as on reproductive outcomes and offspring growth.
