Faculty : Veterinary Medicine

In molecular methods, there is great probability of virus-specific detection and identification. This is due to genus and family specific genome sequences. *In situ* PCR appeared into being to comprise PCR power of amplification and *in situ* hybridization ability to localize target sequence. This new method paves the way to detect minute quantities of nucleic acids in undamaged cells.

The objectives of this study were to develop *in situ* PCR in light microscopy for detection, strains differentiation, and tissue tropism determination of Newcastle disease virus (NDV) and infectious bursal disease virus (IBDV). The method was used to determine pathogenesis of velogenic NDV (vNDV) and very virulent IBDV (vvIBDV) infections.

In the first experiment specific pathogen free (SPF) chickens were infected with vNDV by intranasal administration of 0.1 mL of 10^5 EID₅₀ /0.1 mL of isolate AF2240. Tissue samples were collected and fixed in 10% buffered formalin for histological examination, immunoperoxidase staining (IPS) and *in situ* PCR. *In situ* PCR was successfully developed with probe specific for vNDV. *In situ* PCR (score of 2.17 ± 0.06) was significantly ($p < 0.05$) more sensitive than IPS (score of 1.51 ± 0.40). Histological changes were consistent with the presence of virus.

In the second experiment, SPF chickens were inoculated orally with 0.1 mL of $10^{7.5}$ EID₅₀/mL of vvIBDV (UPM0081 isolate). Tissue samples were collected and fixed in 10% buffered formalin for histological examination, IPS, and *in situ* PCR. *In situ* PCR was developed with probe specific for vvIBDV. *In situ* PCR (score of 2.85 ± 0.29) was significantly ($p < 0.05$) more sensitive than IPS (score of 1.80 ± 0.09). Histological changes were consistent with the presence of virus.

In the third experiment, 24 SPF chickens were infected with vNDV (0.1 mL) by intranasal administration of 10^5 EID₅₀/0.1 mL of vNDV AF2240 isolate. Fifteen SPF chickens were kept as control. Chickens were sacrificed at various intervals and tissue samples were collected for histological examination, IPS, and *in situ* PCR. *In situ* PCR revealed that at hr 2 post inoculation (pi), virus tended to enter trachea and respiratory tract leading to primary viraemia and invading other organs. At hr 4 pi, virus had entered liver and spleen. However, brain and heart were involved only at hr 6 pi. Secondary viraemia probably started as early as hr 12 pi since vNDV was positive in all collected tissues. The study showed the descending order of tissues according to positive signal scoring was: trachea, caecal tonsil, liver, bursa of Fabricius, intestine, proventriculus, lung, spleen, thymus, kidney, heart, and brain. IPS findings were almost similar to *in situ* PCR but less sensitive. Histological changes were consistent with the presence of virus.

In the fourth experiment, 24 SPF chickens were infected with vvIBDV (0.1 mL) by oral administration of $10^{7.5}$ EID₅₀/0.1 mL (UPM0081 isolate). Fifteen SPF chickens were kept as a control group. Chickens were sacrificed at various intervals and tissue samples were collected for histological examination, IPS, and *in situ* PCR. IBDV was detected in intestine, junction of proventriculus and gizzard and caecal tonsil at hr 2 pi using *in situ* PCR leading to primary viraemia and invasion of liver, kidney, and bursa of Fabricius. At hrs 4 and 6 pi, virus reached spleen and thymus, respectively. It was detected in muscle on day 1 pi. Hence, secondary viraemia might occur during the period 12 to 24 hrs pi. Virus tissue tropism was summarized briefly in bursa of Fabricius, thymus, caecal tonsil, liver, junction of proventriculus and gizzard, spleen, kidney, intestine, and muscle. IPS findings indicated sequence of detection of virus, in different tissues, was similar to *in situ* PCR findings. Histological changes were consistent with findings of *in situ* PCR and IPS.

In fifth experiment, 15 SPF chickens were divided into 3 groups. One group was inoculated with vNDV (0.1 mL) by intranasal administration of 10^5 EID₅₀/0.1 mL of vNDV AF2240 isolate, another group was inoculated with lentogenicNDV strain (INDV) (V4 isolate) and a third group was kept as control. Tissue samples were collected for detection of virus by *in situ* PCR with probe specific for vNDV, positive results were obtained only when

tissues were infected with vNDV. Similarly, probe specific for INDV strain showed positive results only for tissues infected with INDV. It demonstrated that specific probes have ability for differentiation of NDV strains.

In the sixth experiment, 15 SPF chickens were divided into 3 groups. One group was inoculated with vvIBDV strain by oral and intraocular administration of 1 mL ($10^{4.83}$ EID₅₀/0.1 mL) of UPM0081 isolate, another group was inoculated with calBDV strain (V877 isolate) and a third group was kept as control. Tissue samples were collected for detection of virus by *in situ* PCR with probe specific for vvIBDV, positive results were obtained only when tissues were infected with vvIBDV. Similarly, probe specific for calBDV strain showed positive results only for tissues infected with calBDV. It demonstrated that specific probes have ability for differentiation of IBDV strains.

It was concluded that the study has successfully developed *in situ* PCR for detection and differentiation of NDV and IBDV strains. *In situ* PCR was more sensitive than IPS in detection of the virus. Tissue tropisms of the virus and disease pathogenesis were established.

Dalam kaedah molikul, terdapat kebarangkalian besar pengesanan dan pengenalan khusus virus. Ini disebabkan oleh genus dan keluarga urutan genom khusus. PCR *in situ* wujud untuk membentuk kuasa PCR penguatan dan kemampuan penghibridan *in situ* untuk mengesan penyentempatan urutan sasaran. Kaedah baharu ini membuka jalan untuk mengesan kuantiti kecil asid nukleik dalam sel yang tidak rosak.

Objektif kajian ini adalah untuk membangunkan PCR *in situ* dalam mikroskopi cahaya untuk pengesanan, pembezaan strain, dan penentuan tropisme tisu virus penyakit Newcastle (NDV) dan virus penyakit bursa berjangkit (IBDV). Kaedah ini digunakan untuk menentukan patogenesis jangkitan velogenik NDV (vNDV) dan sangat getir IBDV (vIBDV).

Dalam eksperimen pertama, ayam bebas patogen khusus (SPF) telah dijangkiti vNDV melalui intranasal (0.1 mL) 10^5 EID50/0.1 mL daripada strain AF2240. Tisu sampel telah dikumpulkan dan diawet dalam 10% formalin berpenimbal untuk pemeriksaan histologi, pewarnaan immunoperoxidase (IPS) dan PCR *in situ*. PCR *in situ* telah berjaya dibangunkan dengan probe yang direka khusus untuk vNDV. PCR *in situ* (2.17 ± 0.06) adalah ketara ($p < 0.05$) lebih sensitif daripada IPS (skor 1.51 ± 0.40). Perubahan histologi adalah konsisten dengan kehadiran virus.

Dalam eksperimen kedua, ayam SPF telah disuntik secara oral dengan 0.1 mL, $10^{7.5}$ EID₅₀/mL vvIBDV asingan UPM0081. Sampel tisu telah dikumpulkan dan diawet dalam 10% formalin berpenimbal untuk pemeriksaan histologi, IPS, dan PCR *in situ*. PCR *in situ* telah dibangun dengan prob yang direka khusus untuk vvIBDV. PCR *in situ* (skor 2.85 ± 0.29) adalah signifikan ($p < 0.05$) lebih sensitif daripada IPS (skor 1.80 ± 0.09). Perubahan histologi adalah konsisten dengan kehadiran virus.

Dalam eksperimen ketiga, 24 ekor ayam SPF telah dijangkiti vNDV (0.1 mL) melalui intranasal (10^5 EID₅₀/ 0.1mL) daripada asingan vNDV AF2240. Lima belas ekor ayam SPF telah diasingkan sebagai kelompok kawalan. Ayam dikorbankan dalam pelbagai jarak dan sampel tisu dikumpulkan untuk pemeriksaan histologi, IPS dan PCR *in situ*. PCR *in situ* menampakkan bahawa pada jam 2 selepas inokulasi (pi), virus cenderung untuk memasuki trakea dan saluran pernafasan menuju ke viraemia primer dan menyerang organ lain. Pada jam 4 pi, virus memasuki hati dan limpa. Bagaimanapun, otak dan jantung terlibat hanya pada jam 6 pi. Viraemia sekunder mungkin bermula seawal jam 12 pi sejak vNDV positif dalam semua tisu yang dikumpulkan. Kajian ini menunjukkan bahawa tertib menurun tisu menurut penskoran signal positif ialah: trakea, tonsil sekum, bursa Fabricius, usus, proventrikulus, peparu, limpa, timus, ginjal, jantung, dan otak. Penemuan IPS hampir serupa dengan PCR *in situ* tetapi kurang sensitif. Perubahan histologi adalah konsisten dengan kehadiran virus.

Dalam eksperimen keempat, 24 ekor ayam SPF dijangkiti vvIBDV (0.1 mL) melalui oral $10^{7.5}$ EID₅₀/0.1 mL (asingan UPM0081). Lima belas ekor ayam SPF telah disimpan sebagai kelompok kawalan. Ayam dikorbankan pada pelbagai jarak dan sampel tisu dikumpulkan untuk pemeriksaan histologi, IPS dan PCR *in situ*. IBDV dikesan di dalam usus, persimpangan proventrikulus dan hempedal dan tonsil sekum pada jam 2 pi menggunakan PCR *in situ* menuju ke viraemia dan menyerang hati, ginjal dan bursa Fabricius. Pada jam 4 dan 6 pi, virus masing-masing mencapai limpa dan timus. Virus dikesan dalam otot pada hari 1 pi. Oleh itu, viraemia sekunder mungkin berlaku dalam tempoh 12 hingga 24 jam pi. Tropisme tisu virus telah diberi ringkasan singkat dalam bursa Fabricius, timus, tonsil sekum, hati, persimpangan proventrikiulus dan hempedal, limpa, usus dan otot. Dapatan IPS menunjukkan urutan pengesanan virus, dalam tisu yang berbeza, adalah sama dengan dapatan PCR *in situ*. Perubahan histologi adalah konsisten dengan penemuan PCR *in situ* dan IPS.

Dalam eksperimen kelima, 15 ekor ayam SPF telah dibahagikan kepada 3 kelompok. Satu kelompok telah disuntik dengan vNDV (0.1 mL) melalui intranasal 10^5 EID₅₀/0.1mL daripada asingan vNDV AF2240, kelompok lain telah disuntik dengan strain lentogenik NDV (INDV) (asingan V4) dan kelompok ketiga disimpan sebagai kelompok kawalan. Sampel tisu yang

dikumpulkan untuk pengesanan virus oleh PCR *in situ* dengan prob khusus bagi vNDV, memperoleh keputusan yang positif hanya untuk tisu yang dijangkiti vNDV. Begitu juga, bagi prob INDV memberi keputusan yang positif hanya untuk tisu yang dijangkiti INDV. Ini menunjukkan bahawa prob khusus mempunyai kemampuan untuk perbezaan strain NDV.

Dalam eksperimen keenam, 15 ekor ayam SPF telah dibahagikan kepada 3 kelompok. Satu kelompok telah disuntik dengan strain vvIBDV melalui oral dan intraokular (1 mL) $10^{4.83}$ EID₅₀/ 0.1mL daripada asingan UPM0081, kelompok lain telah disuntik dengan strain calBDV (asingan V877). dan kelompok ketiga disimpan sebagai kelompok kawalan. Sampel tisu yang dikumpulkan untuk pengesanan virus oleh PCR *in situ* dengan prob khusus bagi vvIBDV, memperoleh keputusan yang positif hanya untuk tisu yang dijangkiti vvIBDV. Begitu juga, bagi prob calBDV memberi keputusan yang positif hanya untuk tisu yang dijangkiti calBDV. Ini menunjukkan bahawa prob khusus mempunyai kemampuan untuk perbezaan strain IBDV.

Kesimpulannya, kajian ini telah berjaya membangunkan PCR *in situ* untuk pengesanan dan pembezaan strain NDV dan IBDV. PCR *in situ* adalah lebih sensitif daripada IPS dalam pengesanan virus. Tisu tropism virus dan patogenesis penyakit telah tertubuh.

ACKNOWLEDGEMENTS

All praise is due to ALLAH and may peace and blessings be upon Mohammed and all his family members and companions.

Also I would like to express my appreciation to main supervisor Professor Dr. Mohd Hair-Bejo who chose me to apply a technique available in a limited number of laboratories all over the world, he has been patient companion and brother and special appreciation to members of supervisory committee, Professor Dr. Abdul Rahman Omar, Professor Datin Paduka Dr. Aini Idris, and Associate Professor Dr. Siti Suri Arshad. I was taught how to be self dependent, how to confront obstacles confidently and never give up. I am grateful to former Dean of School of Graduate Studies, Professor Dr. Hasana M. Ghazali who helped me in registration. Also I remember Associate Professor Dr. Lattifah Hassan and Yousof Yaqub for demonstration of statistical matters. I owe Dr. Majed, Mohammed Ibrahim Saeed, Liew Pit Sze and Lim Jin Nee for cooperation when I applied IPS and PCR, and also Hummaion and Krish for help to design primers.

I am indebted to staff members Saipuzaman Ali, Johari and Mohammed Azri, and my colleagues in laboratory late Amanullah Akhtar, Suhairosinda, Mukminah, Norfitriah, Nurul Syuhada, Nafiu, and Mardhiah who have been helpful and kind.

Then I am very grateful to government of Malaysia which financially supported me via Malaysian International Scholarship. Also special thank to government of Sudan which allow me to study in Malaysia and support me morally and financially.

Family in Sudan, Malaysia, United Arab of Emirates, and USA deserve my sincere respect.

Eventually I would like to thank many people who stood beside me, whose names are absent, however I will never forget them.

I certify that a Thesis Examination Committee has met on 4 January 2017 to conduct the final examination of Hussein Abdallah Elawad Mahmoud on his thesis entitled "Development of in Situ PCR for Virus Detection, Strain Differentiation and Pathogenesis of Newcastle Disease and Infectious Bursal Disease in Chickens" in accordance with the Universities and University Colleges Act 1971 and the Constitution of the Universiti Putra Malaysia [P.U.(A) 106] 15 March 1998. The Committee recommends that the student be awarded the Doctor of Philosophy.

Members of the Thesis Examination Committee were as follows:

Dato' Abdul Rani bin Bahaman, PhD

Professor
Faculty of Veterinary Medicine
Universiti Putra Malaysia
(Chairman)

Mohd Zamri bin Saad, PhD

Professor
Faculty of Veterinary Medicine
Universiti Putra Malaysia
(Internal Examiner)

Jalila binti Abu, PhD

3.4 Scoring of lesions (0-4) detected after HE staining of proventriculus tissue on days 3, 6, and 7 pi of vNDV.	35
3.5 Scoring of lesions (0-3) detected after HE staining of caecal tonsil, brain, liver, and lung tissues on days 3, 6, and 7 pi of vNDV.	36
3.6 Scoring of positive signals (0-3) of IPS applied on different tissues of SPF chickens on days 1, 2, 3, 4, and 5 pi of vvIBDV.	39
3.7 Scoring of positive signals (0-3) of in situ PCR applied on different tissues of SPF chickens on days 1, 2, 3, 4, and 5 pi of vvIBDV.	42
3.8 Scoring of lesions (0-5) detected after HE staining of bursa of Fabricius, thymus, caecal tonsil, and kidney tissues on days 1, 2, 3, 4, and 5 pi of vvIBDV.	47
3.9 Scoring of lesions (0-4) detected after HE staining of junction of proventriculus and gizzard tissue on days 1, 2, 3, 4, and 5 pi of vvIBDV.	48
3.10 Scoring of lesions (0-3) detected after HE staining of liver and spleen tissues on days 1, 2, 3, 4, and 5 pi of vvIBDV.	49
4.1 Pathway of vNDV from hr 2 till day 6 pi by application of IPS.	59
4.2 Numbers and percentages of positive reactions of IPS for detection of vNDV from hr 2 pi till day 6 pi.	60
4.3 Scoring of positive signals of IPS applied on vNDV-infected tissues from hr 2 till day 5 pi.	61

4.4	Intensity of vvIBDV in different infected tissues collected since hr 2 till day 5 pi	62
4.5	Pathway of vNDV from hr 2 till day 6 pi by application of in situ PCR	63
4.6	Numbers and percentages of positive reactions of in situ PCR for detection of vNDV from hr 2 pi till day 6 pi	66
4.7	Scoring of positive signals of in situ PCR applied on vNDV-infected tissues from hr 2 till day 5 pi	67
4.8	Intensity of vNDV in different infected tissues collected since hr 2 till day 5 pi	68
4.9	Appearance of lesions induced by vNDV in different HE-stained tissues from hr 2 till day 5 pi	69
4.10	Numbers and percentages of different vNDV-infected tissues stained with HE in which lesions appeared from hr 2 pi till day 6 pi	73
4.11	Lesion scoring (0-5) of HE stained tissues of trachea, bursa of Fabricius, spleen, and kidney collected from SPF chickens inoculated with vNDV from hr 2 pi till day 5 pi	75
4.12	Lesion scoring (0-4) of HE stained tissues of proventriculus, thymus, and heart collected from SPF chickens inoculated with vNDV from hr 2 till day 5 pi	75
4.13	Lesion scoring (0-3) of HE stained tissues of brain, caecal tonsil, liver, intestine and lung collected from SPF chickens inoculated with vNDV from hr 2 till day 5 pi	75
5.1	Pathway of vvIBDV from hr 2 till day 6 pi by application of IPS.	86
5.2	Numbers and percentages of positive reactions of IPS for detection of vvIBDV from hr 2 pi till day 6 pi	87
5.3	Positive signals scoring (0-3) of IPS on IBDV-infected tissues of SPF chickens.	88
5.4	Intensity of vvIBDV in different infected tissues collected since hr 2 till day 6 pi	89
5.5	Pathway of vvIBDV from hr 2 till day 6 pi by application of <i>in situ</i> PCR	90

5.6	Numbers and percentages of positive reactions of in situ PCR for detection of vvIBDV-infected tissues from hr 2 pi till day 6 pi	94
5.7	Positive signals scoring (0-3) of in situ PCR on IBDV-infected tissues of SPF chickens	95
5.8	Intensity of vvIBDV in different infected tissues collected since hr 2 till day 6 pi	96
5.9	Appearance of lesions induced by vvIBDV in different HE-stained tissues from hr 2 till day 6 pi	97
5.10	Numbers and percentages of different vvIBDV-infected tissues stained with HE in which lesions appeared from hr 2 pi till day 6 pi	101
5.11	Lesions scoring (0-5) of HE stained tissues of bursa of Fabricius, caecal tonsil, thymus, and kidney collected from SPF chickens inoculated with vvIBDV	102
5.12	Lesions scoring (0-4) of HE stained tissues of junction of proventriculus and gizzard collected from SPF chickens inoculated with vvIBDV	102
5.13	Lesions scoring (0-3) of HE stained tissues of liver, spleen, intestine, and muscle collected from SPF chickens inoculated with vvIBDV.	102
6.1	<i>In situ</i> PCR with different probes on vNDV-infected-tissues	113
6.2	<i>In situ</i> PCR with different probes on INDV-infected-tissues	113
6.3	<i>In situ</i> PCR with different probes on vvIBDV-infected-tissues	119
6.4	<i>In situ</i> PCR with different probes on calBDV-infected-tissues	119

LIST OF FIGURES

Figure		Page
1.1	Schematic representation depicting chief stages of direct and indirect RT in situ PCR	3
2.1	Diagrammatic representation of Newcastle disease virus	11
2.2	Segment A and segment B of IBDV	14
3.1	RT-PCR product (591 bp) after amplification of fusion gene involved in RNA extracted from homogenized vNDV-infected-trachea	27
3.2	Brain of SPF chickens on day 7 pi of vNDV. (a) Primary antibody against vNDV, brown colour (arrow) indicates positive result, scoring of 2, scale bar = 20 μ m. (b) Negative control (absence of primary antibody), absence of brown colour, scoring of 0, scale bar = 20 μ m. DAB–peroxidase, hematoxylin counterstain. IPS	28
3.3	Spleen of SPF chickens. (a) Day 3 pi of vNDV. Brown colour (arrow) indicates positive result, scoring of 3.00. Scale bar = 20 μ m (b) Negative control, absence of brown colour, lesion scoring of 0. DAB–peroxidase, hematoxylin counterstain. Scale bar = 20 μ m. IPS	29
3.4	Caecal tonsil of SPF chickens on day 3 pi of vNDV. (a) Probe specific to vNDV, detection of nucleic acid by in situ PCR, purple to blue colour (arrow) indicates positive signals of (NBT/BCIP), scoring of 1.00, scale bar = 10 μ m. (b) Control, absence of probe, absence of positive signal, scoring of 0. Alkaline phosphatase, methyl green counterstain. Scale bar = 10 μ m	30
3.5	Spleen of SPF chickens on day 3 pi of vDV. Probe specific to vvIBDV, dark blue colour (arrow) indicates positive signals. (a) Magnification 40X, scoring of 3.00. Scale bar = 25 μ m (b) Magnification 100X, scoring of 2.00. Scale bar = 10 μ m. (c) Control, non-infected tissue, absence of positive signal, scoring of 0, scale bar = 25 μ m NBT/BCIP–alkaline phosphatase, counterstain methyl green. In situ PCR	31
3.6	Liver of SPF chickens on day 1 pi of vvIBDV. Probe specific to vvIBDV, dark blue colour indicates positive signals. (a) Magnification power 40X, scoring of 2.00. Scale bar = 25 μ m	32

- (b) Magnification power 100X, scoring of 1.00. Scale bar = 10 μm . (C) Negative control, absence of probe, absence of positive signal, scoring of 0. NBT/BCIP–alkaline phosphatase, counterstain methyl green. In situ PCR
- 3.6 Liver of SPF chickens on day 1 pi of vvIBDV. Probe specific to vvIBDV, dark blue colour indicates positive signals. (a) Magnification power 40X, scoring of 2.00. Scale bar = 25 μm (b) Magnification power 100X, scoring of 1.00. Scale bar = 10 μm . (C) Negative control, absence of probe, absence of positive signal, scoring of 0. NBT/BCIP–alkaline phosphatase, counterstain methyl green. In situ PCR 32
- 3.7 Trachea of SPF chickens. (a) Day 3 pi of vNDV. Hyperaemia (black arrow), oedema, hyperplasia (white double arrow), and deciliation (white arrow), lesion scoring of 4.00. Scale bar = 20 μm . (b) Control group, lesion scoring of 0. Scale bar = 20 μm . HE 34
- 3.8 Bursa of Fabricius of SPF chickens. (a) Day 7 pi of vNDV. Scattered lymphocytes (white arrow), increase in size of connective tissue (black arrow), thickening and folded epithelium (blue arrow) and increase in fibroplasia, disruption of follicular physique (red arrow), lesion scoring of 4.00. Scale bar = 20 μm . (b) Control group, lesion scoring of 0. Scale bar = 20 μm . HE 34
- 3.9 Spleen of SPF chickens. (a) Day 7 pi of vNDV. Degeneration and necrosis in a mild focus form and numerous lymphoid follicles in an active form (arrow), lesion scoring of 3.00. (b) Control group, lesion scoring of 0. HE, scale bar = 20 μm 35
- 3.10 Proventriculus of SPF chickens. (a) Day 6 pi of vNDV, destruction of lymphoid area and haemorrhage (arrow), lesion scoring of 3.00, scale bar = 20 μm . (b) Control group, lesion scoring of 0, scale bar = 20 μm . HE 35
- 3.11 Brain of SPF chickens. (a) Day 7 pi of vNDV, endothelial hypertrophy (white arrow) and neuronal necrosis (black arrow), lesion scoring of 2.00. (b) Control group, lesion scoring of 0. HE, scale bar = 100 μm 36
- 3.12 Caecal tonsil of SPF chickens. (a) Day 6 pi of vNDV. Necrosis of lymphoid follicles (arrow), lesion scoring of 3, scale bar = 20 μm . (b) Control group, lesion scoring of 0, scale bar = 20 μm . HE 36

- 3.13 Liver of SPF chickens. (a) Day 6 pi of vNDV. Inflammatory cell infiltration, degeneration and necrosis (arrow), lesion scoring of 3.00, 40x, scale bar = 50 μ m. (b) Control group, lesion scoring of 0. 40x, Scale bar = 40 μ m. HE 37
- 3.14 PCR products resulted from amplification of VP1 and VP2 genes after extraction of RNA from homogenized vvIBDV-invaded-bursa of Fabricius tissue 38
- 3.15 Bursa of Fabricius of SPF chickens. (a) Day 4 pi of vvIBDV, dark brown colour (arrow) indicates positive signals, scoring of 3.00, scale bar = 20 μ m (b) Negative control, absence of brown colour, lesion scoring of 0, scale bar = 20 μ m. DAB–peroxidase, counterstain haematoxylin. IPS 39
- 3.16 Spleen of SPF chickens. (a) Day 2 pi of vvIBDV, brown colour (arrow) indicates positive signals, scoring of 3.00, scale bar = 20 μ m (b) Negative control, absence of brown colour, lesion scoring of 0, scale bar = 20 μ m. DAB–peroxidase, counterstain haematoxylin. IPS 40
- 3.17 Kidney of SPF chickens. (a) Day 2 pi of vvIBDV, brown colour (arrow) indicates positive signals, scoring of 1.00, scale bar = 20 μ m (b) Negative control, absence of brown colour, lesion scoring of 0, scale bar = 20 μ m. DAB–peroxidase, counterstain haematoxylin. IPS 40
- 3.18 Kidney of SPF chickens. (a) Day 2 pi of vvIBDV, brown colour (arrow) indicates positive signals, scoring of 1.00, scale bar = 20 μ m (b) Negative control, absence of brown colour, lesion scoring of 0, scale bar = 20 μ m. DAB–peroxidase, counterstain haematoxylin. IPS 41
- 3.19 Bursa of Fabricius of SPF chickens. (a) Day 5 pi of vvIBDV. Probe specific to vvIBDV, dark blue colour indicates positive signals (arrow), scoring of 3.00. Scale bar = 50 μ m. (b) Magnification 100x. Positive signal (arrow), scoring of 1.00. (c) Negative control, absence of probe, absence of positive signal, scoring of 0, scale bar = 25 μ m. NBT/BCIP–alkaline phosphatase, counterstain methyl green. In situ PCR 43
- 3.20 Caecal tonsil of SPF chickens. (a) Day 2 pi of vvIBDV. Probe specific to vvIBDV, dark blue colour (arrow) indicates positive signals, scoring of 3.00, scale bar = 100 μ m. (b) Negative control, absence of probe, absence of positive signal, scoring of 0. Scale bar = 10 μ m. NBT/BCIP–alkaline phosphatase, counterstain methyl green. In situ PCR 44

- 3.21 Caecal tonsil of SPF chickens on day 2 pi of vvIBDV. Probe specific to vvIBDV, dark blue colour (arrow) indicates positive signals. (a) Magnification power 40X, scoring of 1.00. Scale bar = 25 μm (b) Magnification power 100x, scoring of 3.00. Scale bar = 10 μm . NBT/BCIP–alkaline phosphatase, counterstain methyl green. In situ PCR 44
- 3.22 Junction of proventriculus and gizzard of SPF chickens. (a) Day 2 pi of vvIBDV. Probe specific to vvIBDV, purple colour (arrow) indicates positive signals, scoring of 3.00. (b) Negative control, absence of probe, absence of positive signal, scoring of 0. NBT/BCIP–alkaline phosphatase, counterstain methyl green. In situ PCR, scale bar = 100 μm 45
- 3.23 Junction of proventriculus and gizzard of SPF chickens on day 5 pi. (a) Magnification power 40x. Probe specific to vvIBDV, blue colour (arrow) indicates positive signals, scoring of 3.00. Scale bar = 25 μm . (b) Magnification power 100x. Positive signal (arrow), scoring of 2.00. NBT/BCIP–alkaline phosphatase, counterstain methyl green. In situ PCR, scale bar = 10 μm 45
- 3.24 Liver of SPF chickens on day 1 pi of vvIBDV. Probe specific to vvIBDV, dark blue colour (arrow) indicates positive signals. (a) Magnification 40x, scoring of 2.00. Scale bar = 25 μm (b) Magnification power 100x, scoring of 1.00. Scale bar = 10 μm . (C) Negative control, absence of positive signal, scoring of 0. NBT/BCIP–alkaline phosphatase, counterstain methyl green. In situ PCR 46
- 3.25 Bursa of Fabricius of SPF chickens. (a) Day 4 pi of vvIBDV, severe depletion of lymphoid cells in follicles, necrotic cells and cysts in follicles (black arrow), infiltration of inflammatory cells and fibrous connective tissue in interstitial space (black double arrow), haemorrhage (white arrow), lesion scoring of 5.00. scale bar = 200 μm . (b) Control group, lesion scoring of 0. Scale bar = 100 μm . HE 48
- 4.1 RT-PCR product (591 bp) after amplification of fusion gene involved in RNA extracted from homogenized vNDV-infected-trachea 58
- 4.2 Caecal tonsil of SPF chickens. (a) Hr 2 pi of vNDV. Detection of nucleic acid by in situ PCR. Alkaline phosphatase, purple to blue colour (arrow) indicates positive signals of (NBT/BCIP), scoring of 2.00. (b) Hr 4 p of vNDV. Detection of nucleic acid by in situ PCR. Alkaline phosphatase, purple to blue colour indicates positive signals of (NBT/BCIP) (arrow), scoring of 64

	2.00. (c) Control group, absence of positive signal, scoring of 0.00. Methyl green counterstain. Scale bar = 50 μ m	
4.3	Bursa of Fabricius of SPF chickens. (a) Hr 4 pi of vNDV. Detection of nucleic acid by in situ PCR. Alkaline phosphatase, purple to blue colour (arrow) indicates positive signals of (NBT/BCIP) (arrow), scoring of 2.00. Scale bar = 200 μ m (b) Control group, absence of positive signal, scoring of 0.00. Methyl green counterstain. Scale bar = 50 μ m	65
4.4	Thymus of SPF chickens. (a) Hr 2 pi of vNDV. Detection of nucleic acid by in situ PCR. Alkaline phosphatase, purple to blue colour indicates positive signals of (NBT/BCIP) (arrow), scoring of 2.00. (b) Control group, absence of positive signal, scoring of 0.00. Methyl green counterstain. Scale bar = 25 μ m	65
4.5	Tissues of 3 SPF chickens inoculated with vNDV for observation of lesions after HE staining and detection of virus by IPS and in situ PCR at hr 2 pi	70
4.6	Tissues of 3 SPF chickens inoculated with vNDV for observation of lesions after HE staining and detection of virus by IPS and in situ PCR at hr 4pi	70
4.7	Tissues of 3 SPF chickens inoculated with vNDV for observation of lesions after HE staining and detection of virus by IPS and in situ PCR at hr 6 pi	70
4.8	Tissues of 3 SPF chickens inoculated with vNDV for observation of lesions after HE staining and detection of virus by IPS and in situ PCR at hr 12 pi	71
4.9	Tissues of 3 SPF chickens inoculated with vNDV for observation of lesions after HE staining and detection of virus by IPS and in situ PCR on day 1 pi	71
4.10	Tissues of 3 SPF chickens inoculated with vNDV for observation of lesions after HE staining and detection of virus by IPS and in situ PCR on day 2 pi	71
4.11	Tissues of 3 SPF chickens inoculated with vNDV for observation of lesions after HE staining and detection of virus by IPS and in situ PCR on day 4 pi	72
4.12	Tissues of 3 SPF chickens inoculated with vNDV for observation of lesions after HE staining and detection of virus by IPS and in situ PCR on day 5 pi.	72

5.1	Amplification of VP 1 gene after after extraction of RNA of vvIBDV	85
5.2	Bursa of Fabricius of SPF chickens. (a) Day 2 pi of vvIBDV, probe specific to vvIBDV, dark blue colour indicates positive signals (arrow), scoring of 3.00. (b) Negative control, absence of probe, absence of positive signal, scoring of 0. NBT/BCIP–alkaline phosphatase, counterstain methyl green. In situ PCR, scale bar = 100 µm	91
5.3	Bursa of Fabricius of SPF chickens. (a) Day 1 pi of vvIBDV, probe specific to vvIBDV, dark blue colour indicates positive signals (arrow), scoring of 3.00. scale bar = 50 µm. (b) Hr 6 pi of vvIBDV, purple to blue colour indicates positive signals, scoring of 3.00. NBT/BCIP–alkaline phosphatase, counterstain methyl green. In situ PCR, scale bar = 25 µm	91
5.4	Thymus of SPF chickens. (a) Hr 12 pi of vvIBDV, probe specific to vvIBDV, dark blue colour indicates positive signals (arrow), scoring of 2.00. scale bar = 25 µm. (b) Negative control, absence of probe, absence of positive signal, scoring of 0. NBT/BCIP–alkaline phosphatase, counterstain methyl green. In situ PCR, scale bar = 25 µm	92
5.5	Junction of proventriculus and gizzard of SPF chickens. (a) Hr 2 pi of vvIBDV, probe specific to vvIBDV, dark blue colour indicates positive signals(arrow), scoring of 1.00. Scale bar = 100 µm. (b) Negative control, absence of probe, absence of positive signal, scoring of 0. NBT/BCIP–alkaline phosphatase, counterstain methyl green. In situ PCR, scale bar = 50 µm	92
5.6	Junction of proventriculus and gizzard of SPF chickens on day 2 pi of vvIBDV, probe specific to vvIBDV. (a) Magnification power 40X, probe specific to vvIBDV, dark blue colour indicates positive signals (arrow), scoring of 3.00. Scale bar = 25 µm. (b) Magnification power 100x, probe specific to vvIBDV, purple to blue colour indicates positive signals (arrow), scoring of 2.00. Scale bar = 10 µm. NBT/BCIP–alkaline phosphatase, counterstain methyl green. In situ PCR.	93
5.7	Tissues of 3 SPF chickens in which vvIBDV was inoculated for application of HE staining, IPSand in situ PCR at hour 2 pi.	98
5.8	Tissues of 3 SPF chickens in which vvIBDV was inoculated for application of HE staining, IPS and in situ PCR at hour 4 pi	98
5.9	Tissues of 3 SPF chickens in which vvIBDV was inoculated for application of HE staining, IPSand in situ PCR at hr 6 pi	98

5.10	Tissues of 3 SPF chickens in which vvIBDV was inoculated for application of HE staining, IPSand in situ PCR at hr 12 pi	99
5.11	Tissues of 3 SPF chickens in which vvIBDV was inoculated for application of HE staining, IPS and in situ PCR on day 1 pi	99
5.12	Tissues of 3 SPF chickens in which vvIBDV was inoculated for application of HE staining, IPSand in situ PCR on day 2 pi	99
5.13	Tissues of 3 SPF chickens in which vvIBDV was inoculated for application of HE staining, IPS and in situ PCR on day 4 pi	100
5.14	Tissues of 3 SPF chickens in which vvIBDV was inoculated for application of HE staining, IPSand in situ PCR on day 6 pi	100
6.1	RT-PCR product (591 bp) after amplification of fusion gene involved in RNA extracted from homogenized vNDV-infected-trachea and RNA extracted from lentogenic NDV strain (V4 isolate)	112
6.2	Caecal tonsil of SPF chickens on day 5 pi of lentogenic strain of NDV. (a) Probe specific to lentogenic strain, positive signals in dark blue colour (arrows), scale bar = 100 µm. (b) probe specific to velogenic strain, negative result. Scale bar = 100 µm. (c) Probe on control tissue, negative result. Scale bar = 200 µm. Counterstain methyl green. In situ PCR	114
6.3	Trachea of SPF chickens on day 5 pi of velogenic strain of NDV. (a) Probe specific to velogenic strain, positive signals in blue colour (arrows), scale bar = 100 µm. (b) Probe specific to lentogenic strain, negative result, scale bar = 50 µm. Counterstain methyl green. In situ PCR	115
6.4	Brain of SPF chickens on day 5 pi of velogenic strain of NDV. (a) Probe specific to velogenic strain, positive signals in blue colour (arrows), scale bar = 100 µm. (b) Probe specific to lentogenic strain, negative result, scale bar = 100 µm. Counterstain methyl green. In situ PCR	115
6.5	Thymus of SPF chickens on day 5 pi of velogenic strain of NDV. (a) Probe specific to velogenic strain, positive signals in blue colour (arrows), scale bar = 100 µm. (b) Probe specific to lentogenic strain, negative result, scale bar = 100 µm. Counterstain methyl green. In situ PCR	116
6.6	Four different primers were designed for amplification of VP 1 gene of calBDV (V877 isolate)	117

6.7	PCR product of 430 bp resulted from amplification of VP 1 gene of calBDV (V877 isolate) for preparation of probe	117
6.8	RT-PCR product (512 bp) after amplification of VP1 involved in RNA extracted from homogenized vvIBDV-invaded-bursa of Fabricius tissue	118
6.9	Bursa of Fabricius of SPF chickens on day 4 pi of calBDV. (a) Probe specific to classical strain, positive signals (dark blue colour) (arrow), scale bar = 100 μ m. (b) Probe specific to very virulent strain, negative result, scale bar = 200 μ m. (c) Probe on control tissue, negative result, scale bar = 25 μ m. Counterstain methyl green. In situ PCR	120
6.10	Liver of SPF chickens on day 4 pi of caBDV. (a) Probe specific to classical strain, positive signals (dark blue colour) (arrow), scale bar = 50 μ m. (b) Probe specific to very virulent strain, negative result, scale bar = 50 μ m. (c) Probe on control tissue, negative result, scale bar = 50 μ m. Counterstain methyl green. In situ PCR. 179	121
6.11	Spleen of SPF chickens on day 4 pi of calBDV. (a) Probe specific to classical strain, positive signals (dark blue colour) (arrow), scale bar = 25 μ m. (b) Probe on control tissue, negative result, scale bar = 25 μ m. Counterstain methyl green. In situ PCR	122
6.12	Thymus of SPF chickens on day 4 pi of calBDV. (a) Probe specific to classical strain, positive signals (dark blue colour) (arrow), scale bar = 100 μ m. (b) Probe specific to very virulent strain, negative result, scale bar = 100 μ m. Counterstain methyl green. In situ PCR	122

LIST OF ABBREVIATIONS

APMV-1	Avian paramyxovirus serotype 1
BALT	Bronchial associated lymphoid tissues
bp	Base pair
CD	Cluster of differentiation CD4+ and CD8+ T lymphocytes
caIBD	Classical infectious bursal disease strain
cDNA	Complementary deoxy ribonucleic acid
DAB	Diaminobenzidine
DIG	Digoxigenin
DNA	Deoxy ribonucleic acid
EID50	Egg infective dose by 50%
F gene	Fusion gene
g	Gram
GALT	Gut (Gastrointestinal tract) associated lymphoid tissue
G-C	Guanine-cytosine
HE	Haematoxylin and eosin
HIV	Human immunodeficiency virus
IBD	Infectious bursal disease
ICPI	Intracerebral pathogenicity index
IgM+	Immunoglobulin M
IPS	Immunoperoxidase staining
INDV	Lentogenic Newcastle disease virus strain
MALT	Mucosa-associated lymphoid tissues
mL	Millilitre
mRNA	Messenger ribonucleic acid
NBT/BCIP	Nitroblue tetrazolium 5 - bromo 4 - chloro 3 - indolyl phosphate
ND	Newcastle disease

NDV	Newcastle disease virus
nt	Nucleotide
OIE	<i>Office Internationale des Epizooties</i>
PB	Phosphate buffer
PBS	Phosphate buffered saline
PCR	Polymerase chain reaction
pi	Post-inoculation
RNA	Ribonucleic acid
RT-PCR	Reverse transcription- polymerase chain reaction
SDS	Sodium dodecyl sulphate
SE	Standard error
SPF	Specific pathogen free
SSC	Saline sodium citrate
vNDV	Velogenic Newcastle disease virus strain
vvIBD	Very virulent infectious bursal disease strain
WB	Western Blot
µl	Microlitre
µm	Micrometre

CHAPTER 1

INTRODUCTION

Rapid change was observed in production of animal products, processing, consumption and marketing and rapid growth was observed in livestock production over last four decades (Narrod *et al.*, 2007). At present, consumption in developing countries is roughly one-third the meat and one-quarter of the milk products *per capita* compared to consumption in the richer North. By 2020, developing countries contribution to whole world meat consumption will be 63% instead of 52% right now. By 2020, consumption of meat and consumption of milk in developing countries will increase 107 and 177 million metric tons (mmt), respectively, more than it was in 1996/1998 (Delgado, 2003). However, poultry has been leading growth in livestock production in both developed and developing countries. There was an increase in poultry meat production in East and South East Asia and in Latin America particularly in China and Brazil (Narrod *et al.*, 2007). It was anticipated that an increase of 3.6 to 3.5% *per annum* would ensue in poultry meat production and consumption in developing countries between 2005 and 2030. Rise is attributed to introduction of modern methods of intensive production, genetic improvements, improvement in preventive applications, disease control and biosecurity measures, elevation in income and human population, and urbanization (Narrod *et al.*, 2007).

On the other hand, chickens, in all corners of the world, are permanently exposed to diseases of various kinds. Diseases sometimes have regional impact or even an impact on world trade. Namely, some diseases cause catastrophic consequences such as highly pathogenic avian influenza (HPAI strain H5N1), which is expected to threaten poultry industry throughout current century. Other examples of threats comprise Newcastle disease (ND), which is endemic all over the world, and infectious bursal disease (IBD). In general, great losses are associated with flock mortality, disruption in supply to markets, declines in consumption and seriously affected profitability. All these factors stimulate investment and scientific research in diagnostic resources to result in available sophisticated diagnostic procedures (Simon and Durham, 2010).

Diagnostic virology, on its long way of progress, encountered numerous landmarks; starting with tissue culture, cell culture, histopathology, electron microscopy and serology to end up with molecular diagnosis. Molecular methods are characterized by ability to detect viable viruses and even dead viruses which are impossible to cultivate. In molecular methods, there is great probability of virus-specific detection and identification. This is due to genus and family specific genome sequences (Storch, 2000). Polymerase

chain reaction (PCR), with resounding fame for almost two decades, is still not satisfactory to morphologists whose interests are associated with conserved tissues (Morel and Raccurt, 2003). Direct hybridization assays without amplification suffers from lack of sensitivity (Storch, 2000). Then *in situ* PCR appeared into being to comprise PCR power of amplification and *in situ* hybridization ability to localize a target sequence. This new method paved way to detect minute quantities of nucleic acids in undamaged cells (Morel and Raccurt, 2003). But, *in situ* PCR is still in stage of development. It requires more refining (Takeuchi *et al.*, 2006). *In situ* PCR technique has recently been developed to allow performance of a reaction directly on tissue. An exquisitely sensitive detection of viral nucleic acid is carried out in tissues, whereas, this technique is done in a few number of laboratories at present (Storch, 2000). It is hoped that this technique will allow detection of extremely low levels of nucleic acids, subsequently investigation of early pathogenesis (Zhang *et al.*, 2002). Exquisiteness of *in situ* PCR was verified by Zhang *et al.* (2002) when they managed to detect IBDV at 6 hours, 12 hours, 16 hours, 28 hours post-infection in the bursa of Fabricius, caecal tonsil, thymus and spleen, liver, kidney and thigh muscle. In comparison to *in situ* hybridization which was applied for detection of IBDV in tissues collected 40 hour pi (Zhang *et al.*, 2002). In other study conducted by Brown *et al.* (1999), *in situ* hybridization was applied for detection of 3 different isolates of viscerotropic velogenic ND virus (vvNDV) on day 2 pi, zero out of 3 isolates were detected on brain and heart, 1 out of 3 isolates was detected in arosac and lung and 3 out 3 isolates were detected in eyelid, spleen and caecal tonsil.

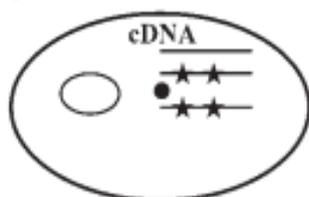

Bagasra *et al.* (1992) found that *in situ* PCR has greater potential to determine actual proviral load in peripheral blood at various stages of HIV-1 infection. Furthermore, it has a potential power to evaluate efficacy of various therapeutic interventions. Even some entities in latent or defective forms could be detected. Determination of location of a target sequence in a certain tissue is carried out by using two labeled probes; one probe with a certain colour complementary to infectious agent and another probe with another colour complementary to gene of infected cell (Morel and Raccurt, 2003). There are two types of *in situ* PCR (Figure 1.1); in first type, direct *in situ* PCR; primers themselves, which are used for amplification, are labeled with either biotin or digoxigenin (DIG), or other fluorescein compounds. Here, labeled nucleotide is fused into amplified products during the process of amplification. At the end of reaction, labeled products are visualized with the help of immunohistochemistry (Muro-Cachu, 1997; Takeuchi *et al.*, 2006).

Direct RT *in situ* PCR

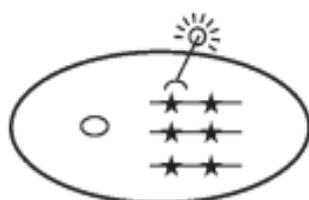

1. mRNA is converted to cDNA

2. PCR amplification by using labeled nucleotide or labeled primers.

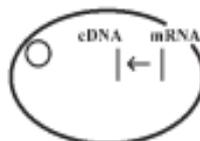

3. Detection of the label

Indirect RT *in situ* PCR

1. mRNA is converted to cDNA

2. Amplification of cDNA by PCR

3. Hybridization of labeled probes with amplified gene products

4. Detection of the label

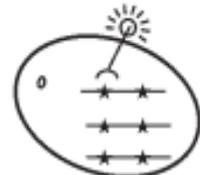

Figure 1.1 : Schematic representation depicting chief stages of direct and indirect RT *in situ* PCR. First, conversion of mRNA to cDNA. Second, amplification; in direct technique; it is labeled amplified product as a result of labeled primer or labeled nucleotide, subsequently, detection by immunohistochemistry; while in indirect technique, conventional amplification is followed by hybridization of labeled probe with PCR product, thus, immunohistochemical detection (Takeuchi *et al.*, 2006).

Tereza *et al.* (2008) applied direct *in situ* RT-PCR method and managed to successfully detect, with higher sensitivity than conventional RT-PCR and virus isolation, very virulent IBDV (vvIBDV) from bursa of Fabricius, thymus and liver from IBDV-suspected infection in birds. Primers for *in situ* PCR in such study were labeled with biotin. This technique might clarify uncertain details related to replication and pathogenesis of vvIBDV in chicken.

Second type of *in situ* PCR is indirect; here PCR is carried out with unlabeled primers; then, products of amplification are hybridized with a labeled probe. Then products after hybridization could be observed with immunohistochemistry (Takeuchi *et al.*, 2006). In other words, when amplification step has finished, labeled nucleotides (digoxigenin-11-dUTP)

are incorporated, thus, consequents are detected by immunohistochemistry. In brief, amplified product is detected by *in situ* hybridization with the help of labeled probes (Figure 1.1). Privilege of *in situ* PCR over *in situ* hybridization is that it allows detection of minimal amount of nucleic acid (Muro-Cachu, 1997). In general, this technique is influenced by target accessibility, probe concentration, hybridization stringency (melting temperature, base composition, specificity of sequence between target and probe, composition of hybridization/washing solution), and kind of label (Muro-Cachu, 1997).

Newcastle disease (ND) and infectious bursal disease (IBD) still lack deep research to comprehend some points in pathogenesis such as why in some NDV isolates, amino acids sequence is similar to sequences in different strains (de Leeuw *et al.*, 2003; Brown, 1999). Absence of glycosylation sites in HN protein, how it causes alteration of pathogenicity (Panda *et al.*, 2004). How V protein (P gene product) participates in NDV virulence (Huang *et al.*, 2003), and how some isolates change behavior of virulence from mild to severe (Kommers *et al.*, 2002). Also, what the mechanism of haemorrhage in IBD is (Zeryehun *et al.*, 2012). How significant IBDV plays role in apoptosis process (Nieper *et al.*, 1999). How long it takes for IBDV to reach target tissues and subsequently how soon other processes of pathogenesis start (Zhang *et al.*, 2002). Hybridization technique with specific probes for certain virus strains was applied successfully for differentiation between NDV or IBDV strains by Li and Zhang (2004) and Kataria *et al.* (2000), respectively. It was the hypothesis of present study that *in situ* PCR technique, with the same specific probes, is capable of differentiation of NDV strains and IBDV strains. Moreover, pathogenesis of disease and tissue tropism of the virus could be determined accurately using *in situ* PCR technique.

The objectives of this study were:

- 1) to develop RT *in situ* PCR in light microscopy for detection of NDV and IBDV.
- 2) to determine the tissue tropism of velogenic NDV and very virulent IBDV by application of *in situ* PCR.
- 3) to determine the pathogenesis of velogenic NDV and very virulent IBDV infections by *in situ* PCR.
- 4) to apply *in situ* PCR for differentiation between NDV strains and IBDV strains.
