**Chairman: Mohamad Rushdan Md Said, Ph.D.**  
**Faculty: Institute For Mathematical Research**

Elliptic curve cryptosystem (*ECC*) is being used nowadays more than ever to fulfill the need for public key cryptosystem because of its ability to use shorter keys lengths and computationally more efficient algorithms than another public key cryptosystems such as Rivest-Shamir-Adleman (*RSA*), Digital Signature Algorithm (*DSA*) and *ElGamal*. The most time consuming operation in *ECC* is elliptic curve scalar multiplication (*ECSM*). Many research have been carried out to accelerate this operation. The structure of the *ECSM* involves three mathematical levels: finite field arithmetic, point arithmetic and scalar arithmetic. The purpose of this work is to study different issues that arise in the efficient implementation of *ECSM* over prime field, specifically targeting the point and scalar arithmetic levels over elliptic curve.

At the point arithmetic level, we introduce the 4– dimensional Jacobian coordinates system ( $4 - DJC$ ), where a point  $(X, Y, Z, T)$  with  $Z \neq 0$  and  $T = Z^2$ , corresponds to affine point  $(X/T, Y/Z^3)$  and satisfying the elliptic curve equation over prime field. This is due to the expensive cost of the field multiplication inversion involves in both point doubling and point addition operation with the arithmetic of the affine coordinates  $(x, y)$ . This system has proven their efficiency in many contexts that is to reduce the number field operation for point doubling opera-

tion in comparison with point doubling operation using projective coordinates system and Jacobian coordinates system respectively, to reduce the number field operation for point addition operation in comparison with point addition operation using Jacobian coordinates system and to reduce the cost of computing point addition using mixed coordinates technique, also in comparison with using Jacobian coordinates in mixed coordinates technique.

At the scalar arithmetic level, we develop three new algorithms to accelerate the *ECSM* using the non adjacent form (*NAF*), window  $\omega$  – non adjacent form ( $\omega - NAF$ ) and direct recoding method (*DRM*), by rewriting the scalar involved in *ECSM*. The proposed algorithm using *NAF* to represent the scalar in *ECSM* reduced the cost of computation of the *ECSM* by comparing with using the binary and *NAF* algorithm respectively. The second proposed algorithm which is using  $\omega - NAF$  reduced the cost of computation of the *ECSM* by comparing with using the binary, *NAF* and  $\omega - NAF$  algorithm with  $\omega = 3$  respectively. Finally, the proposed two algorithms using *DRM* to represent the scalar in *ECSM* involve binary form and *NAF*. The computational complexity of this proposed methods have high performance when computing the *ECSM* compared to the other methods. This is due to the number of operations required for execution is less comparing with using the mutual opposite form (*MOF*).

This thesis shows how we can serve the public key cryptosystems by speeding up the *ECSM* operation by reducing operations in point and scalar arithmetic levels.

Abstrak tesis yang dikemukakan kepada Senat Universiti Putra Malaysia  
sebagai memenuhi keperluan untuk ijazah Doktor Falsafah

**PEMBANGUNAN SUATU KAEDAH PENDARABAN SKALAR  
UNTUK KELUK ELIPTIK YANG PANTAS DAN CEKAP DALAM  
MEDAN PERDANA**

Fakulti: Institut Penyelidikan Matematik**

Sistem krypto Lengkungan eliptik (*ECC*) digunakan pada masa kini lebih daripada biasa untuk memenuhi keperluan untuk sistem kunci umum kerana keupayaannya untuk menggunakan kepanjangan kekunci lebih pendek dan algoritma pengiraannya lebih cekap daripada sistem krypto kunci awam seperti Rivest - Shamir - Adleman (*RSA*), Digital Algoritma Tandatangan (*DSA*) dan *ElGamal*. Yang paling memakan masa dalam operasi *ECC* adalah gandaan lengkungan eliptik skalar (*ECSC*). Banyak kajian telah dijalankan untuk mempercepatkan operasi ini. Struktur ini melibatkan tiga tahap matematik: aritmetik medan terbatas, titik aritmetik dan aritmetik skalar. Tujuan kajian ini ialah untuk mengkaji isu-isu yang berbeza yang timbul dalam pelaksanaan kecekapan keatas medan- medan perdana, khususnya mensasarkan titik dan peringkat aritmetik skalar sepanjang lengkungan eliptik.

Di peringkat aritmetik titik, kami memperkenalkan sistem dimensi Koordinat Jakobian ( $4-DJC$ ), di mana satu mata  $(X, Y, Z, T)$  dengan  $Z \neq 0$  dan  $T = Z^2$ , sepadan dengan titik afin  $(X/T, Y/Z^3)$  dan memuaskan persamaan lengkungan eliptik berbanding medan perdana. Ini adalah kerana kos yang mahal daripada penyongsangan medan melibatkan pengandaan dalam kedua-dua mata dua kali ganda dan titik operasi tambahan dengan satu aritmetik Koordinat afin  $(x, y)$ . Sistem ini telah membuktikan kecekapan mereka dalam banyak konteks iaitu untuk mengurangkan operasi medan nombor untuk operasi mata dua kali ganda

berbanding dengan operasi mata dua kali ganda menggunakan masing-masing sistem Koordinat projektif dan Sistem Koordinat Jacoban, untuk mengurangkan operasi medan nombor untuk operasi tambahan mata berbanding dengan titik operasi Selain menggunakan sistem Koordinat Jacoban dan mengurangkan kos tambahan mata pengkomputeran menggunakan teknik campuran koordinat, turut membandingkan dengan menggunakan Koordinat Jacoban dalam teknik campuran koordinat.

Di peringkat aritmetik skalar, kami membangunkan tiga algoritma baru untuk mempercepatkan *ECSM* menggunakan bentuk yang bukan bersebelahan (*NAF*), tingkap  $\omega$ -bentuk bukan bersebelahan ( $\omega$ -*NAF*) dan kaedah rekod secara langsung (*DRM*), dengan menulis kembali skalar yang terlibat dalam proses tersebut *ECSM*. Algoritma yang dicadangkan, *NAF* digunakan untuk mewakili skalar dalam *ECSM* mengurangkan kos pengiraan *ECSM* dengan membandingkan dengan menggunakan binari dan algoritma *NAF* masing-masing. Cadangan Algoritma kedua yang  $\omega$  - *NAF* digunakan mengurangkan kos pengiraan dengan membandingkan penggunaan binari, *NAF*, algoritma  $\omega$  - *NAF* dan  $\omega = 3$  masing-masing. Akhir sekali, mencadangkan dua algoritma *DRM* yang digunakan untuk mewakili skalar *ECSM* dalam melibatkan bentuk binari dan *NAF*. Kerumitan pengiraan bagi kaedah yang dicadangkan ini mempunyai prestasi yang tinggi apabila pengiraan *ECSM* berbanding dengan kaedah lain. Ini disebabkan oleh bilangan operasi yang diperlukan untuk pelaksanaan adalah kurang berbanding dengan menggunakan bentuk bertentangan bersama (*MOF*).

Tesis ini menunjukkan bagaimana kita boleh memberi khidmat kepada cryptosystems umum utama dengan mempercepatkan *ECSM* operasi dengan mengurangkan operasi di tempat dan tahap aritmetik skalar.

## ACKNOWLEDGEMENTS

All praise and thanks be to Almighty Allah, the most Gracious, the most Merciful. I seize this opportunity to express that it is a great pleasure and honour for me to thank those who made this doctoral thesis possible.

First and foremost, my deepest appreciation, gratitude and respect to my supervisor, Associate Professor Dr. Mohamad Rushdan B Md Said for his patience and allowing me the space to develop my ideas. Without his tremendous help, I could not have completed this doctoral study.

I am thankful to the members of my thesis committee: Professor Dr. Isamiddin S. Rakhimov and Associate Professor Dr. Muhammad Reza Bin Kamel Ariffin for their useful comments and discussions during my doctoral study.

The Institute For Mathematical Research provided a wonderful atmosphere during my doctoral studies. It was a pleasure being part of a group where students, faculty and staff have a number of occasions to get together and become better friends.

I also want to thank my country, Iraq and especially the Ministry of Higher Education and Scientific Research for giving me this opportunity to achieve this personal goal in life and reinforcing my commitment to contribute toward the development and progress of my country.

I owe a lot of thanks to my friends, for their support and friendship, especially in tough times, which means a lot to me.

Warm thanks to my father, brothers and sisters who have motivated me to do my best and have always been extraordinary examples for me.

Finally, I will always have the greatest love for my late mother and sister who gave me so much love, encouragement and intellectual motivation throughout the last few years to overcome my nostalgia and loneliness and enable me to complete this work as soon as possible. I deeply miss them.

I certify that a Thesis Examination Committee has met on 23/2/2015 to conduct the final examination of Najlae Falah Hameed Al-Saffar on her thesis entitled "Development of Some Fast and Efficient Methods for Elliptic Curve Scalar Multiplication over Prime Fields" in accordance with the Universities and University Colleges Act 1971 and the Constitution of the Universiti Putra Malaysia [P.U.(A) 106] 15 March 1998. The Committee recommends that the student be awarded the degree of Doctor of Philosophy).

Members of the Thesis Examination Committee were as follows:

**Mahendran Shitan, Ph.D.**

Associate Professor  
Institute for Mathematical Research  
Universiti Putra Malaysia  
(Chairperson)

**Ibragimov Gafurjan, Ph.D.**

## Declaration by Graduate Student

I hereby confirm that:

- This thesis is my original work;
- Quotations, illustration and citations have been duly referenced;
- The thesis has not been submitted previously or concurrently for any other degree at any institutions;
- Intellectual property from the thesis and copyright of thesis are fully-owned by Universiti Putra Malaysia, as according to the Universiti Putra Malaysia (Research) Rules 2012;
- Written permission must be obtained from supervisor and the office of Deputy Vice-Chancellor (Research and Innovation) before thesis is published (in the form of written, printed or in electronic form) including books, journals, modules, proceedings, popular writings, seminar papers, manuscripts, posters, reports, lecture notes, learning modules or any other materials as stated in the Universiti Putra Malaysia (Research) Rules 2012;
- There is no plagiarism or data falsification/fabrication in the thesis, and scholarly integrity is upheld as according to the Universiti Putra Malaysia (Graduate Studies) Rules 2003 (Revision 2012-2013) and the Universiti Putra Malaysia (Research) Rules 2012. The thesis has undergone plagiarism detection software.

## CHAPTER 1

### INTRODUCTION

#### 1.1 Cryptography

Cryptography is the art and science of using mathematics to exchange messages parties authorized in a secret way to make it either impossible or computationally infeasible for unauthorized parties to do so (Yan, 2002; Mollin, 2010). The word cryptography is derived from Greek words: "kryptós", meaning hidden, and "graphein", meaning to write. The science of discovering weaknesses in methods used to exchange messages in secret is named cryptanalysis. This word also came from the Greek words also: "kryptós" and "analýein", meaning to loosen. Cryptography and cryptanalysis are subordinate to a more general term which is cryptology. That is, cryptology is the mathematical science of studying cryptography and cryptanalysis (Spillman, 2004; Oppliger, 2011). Cryptology also comes from the Greek words: "kryptós" and "lógos", meaning word, which is considered as the original intent on cryptology, in other words, it implies protecting the confidentiality of the data.

**Figure 1.1: The Relationship Between Cryptology, Cryptography and Cryptanalysis**

According to the literatures (Raphael and Sundaram, 2011; Poonia et al., 2013; Challita and Farhat, 2011), cryptography comprises steganography, which is a technique of hiding a file within another one, in way it cannot be seen. As an example would be invisible ink. The hidden file could be recovered by the attacker if he detect that steganography has been used (invisible ink) to be able to read the hidden file. While the objective of the cryptography is to make the message unreadable to anyone who does not have the key and know the correct algorithm.

The oldest evidence of using cryptography was found in a tomb of the nobleman Khnumhotep II in Egypt around 1900 B.C. (Damico, 2009; Gebbie, 2003). At that time the purpose was not to make the messages unreadable, but could also be to change its form in a way which would make it appear dignified. Modern cryptography is involved in ensuring secrecy of messages between military leaders, spies, and diplomat, so as to guarantee secure of exchange of confidential communication. In recent decades, people have employed cryptography for phone, fax, email communication, bank transactions, and credit card transactions on the web. It is also employed for a variety of information security issues including electronic signatures, which are used to prove who sent a message. In brief, cryptography has become a very common practice in internet based communications.

Cryptography plays an important role in providing security, by offering a high degree of security and flexibility. In addition to the fact that cryptography is a tool to protect the confidentiality of data, data integrity, authentication and non repudiation are other important goals of cryptography.

- In terms of confidentiality, the goal is to keep the content of information from all but those who are authorized to have it.
- In terms of data integrity, the goal is to be able to detect alteration of data.
- In terms of authentication, the goal is to be able to identify entities in communication.
- Finally, in terms of non repudiation, the goal is to prevent an entity from denying previous commitments or actions.

Three important issues are involved when dealing with the cryptography: encryption, decryption (usually defined by cryptographic systems

or cryptosystems) and the key. Encryption is the process of encoding messages or information in such a way that only authorized parties can read it. Decryption is the process of decoding data that have been encrypted using encryption process. These two processes (encryption and decryption) would produce no useful result without a key. So, in encryption process, a key specifies the particular transformation of plaintext (that needs to be encrypted) into ciphertext (that has been encrypted), or vice versa during decryption process. The processes of encryption and decryption are shown in Figure 1.2 below.

**Figure 1.2: The Encryption and Decryption Process**

There are two main different types of cryptosystems: private key cryptosystem and public key cryptosystem. In the private key system, the same key is used in the process of both encryption and decryption. This key must be kept as a secret by all parties involved in the communication. However, the disadvantage of this system is the risk of interception of the key by an attacker in the key exchange process. This problem has been dealt with by public key cryptosystem. The next two subsection cover these cryptographic systems in detail.

### 1.1.1 Private Key Cryptosystem

Conventional private key cryptosystem (also commonly known as a symmetric or secret key cryptosystem) is the type in which the same key is involved in the processing of encryption and decryption. That is, this key should be agreed to by the one who needs to encrypt and the one who needs to decrypt. The process of the encryption of the plain text to the cipher text is as follows:

The sender will define an invertible function  $f$  as

$$f : \mathcal{M} \xrightarrow{k} \mathcal{C}, \quad (1.1)$$

where  $\mathcal{M}$  is the set of plain texts, and  $\mathcal{C}$  is the set of cipher texts.

In order to produce the cipher text, compute

$$C = f_k(M), \quad \text{for } M \in \mathcal{M} \text{ and } C \in \mathcal{C}, \quad (1.2)$$

The  $C$  will be transmitted over the public channel to the receiver, together with the key  $k$  but over a secure channel. When the receiver gets the cipher text  $C$ , he would be able to decrypt it as follows:

The receiver will use  $f^{-1}$  which is defined by

$$f^{-1} : \mathcal{C} \xrightarrow{k} \mathcal{M}, \quad (1.3)$$

to compute

$$\begin{aligned} f_k^{-1}(C) &= f_k^{-1}(f_k(M)) \\ &= M \end{aligned} \quad \text{for } M \in \mathcal{M} \text{ and } C \in \mathcal{C}, \quad (1.4)$$

Although the performance of the private key cryptosystem is very fast and it has been well tested, the key should be stored securely and exchanged within a secure channel. A stream cipher is one of the examples of a private key cryptosystem.

### 1.1.2 Public Key Cryptosystem

The idea and concept of a public key cryptosystem (also known as an asymmetric key cryptosystem) was introduced by Diffie and Hellman (1976), when they proposed the Diffie Hellman key exchange (*DHKE*) to exchange keys. In a public key cryptosystem, two different keys are involved for the processing of encryption and decryption. One key is considered as a public key and the second key will be kept secure.

**Definition 1.1 :** A one way function is a function  $f$  such that for each  $x$  in the domain of  $f$ , it is easy to compute  $f(x)$ ; but for essentially all  $y$  in the range of  $f$ , it is computationally infeasible to find any  $x$  such that  $y = f(x)$

**Definition 1.2 :** A one way function  $f : X \rightarrow Y$  is said to be a trapdoor one way function if there exist some information with which  $f$  can be efficiently inverted. This additional information is known as a trapdoor.

**Example 1.1** The function  $f_{k,n} : x \rightarrow x^k \pmod n$  is a trapdoor one way function, where  $n = pq$  with  $p$  and  $q$  being two primes. As it is easy to compute since the modular exponentiation  $x^k \pmod n$ , then the computation of  $f$  is easy. But  $f^{-1}$  is difficult to compute. However, if  $k'$  the trapdoor is given, then  $f$  can be easily inverted, since  $(x^k)^{k'} = x$

**Definition 1.3 :** A public key cryptosystem, comprises a family  $f_k : \mathcal{M} \rightarrow \mathcal{C}$  of trapdoor one way functions.

The process of encrypting the plain text to the cipher text is as follows:  
The sender will define an invertible function  $f$  as

$$f : \mathcal{M} \xrightarrow{e_k} \mathcal{C}, \quad \text{where } e_k \text{ is the public key} \quad (1.5)$$

If he wants to produce the cipher text, he will compute

$$C = f_{e_k}(M), \quad \text{for } M \in \mathcal{M} \text{ and } C \in \mathcal{C}, \quad (1.6)$$

The  $C$  will be transmitted over the public channel to the receiver. When the receiver gets the cipher text  $C$ , he would be able to decrypt it as follows:

The receiver will use his private key  $(d_k)$  and  $f^{-1}$  which is defined by

$$f^{-1} : \mathcal{C} \xrightarrow{d_k} \mathcal{M}, \quad (1.7)$$

to compute

$$\begin{aligned} f_{d_k}^{-1}(C) &= f_{d_k}^{-1}(f_{e_k}(M)) \\ &= M \end{aligned} \quad \text{for } M \in \mathcal{M}, \quad C \in \mathcal{C} \text{ and } e_k \neq d_k, \quad (1.8)$$

The public key cryptosystem increases the security and convenience, where the two parties do not have any kind of previous communication. (For example, such as the communication which happens between members in a bank, if user wants to communicate with the specific user. This will cost only the application of the information in data bank.) That is, public key cryptosystems have some important advantages over private key cryptosystems in the distribution of the keys. However, it might be slow when a large amount of information needs to be exchanged securely.

A public key cryptosystem is based on the computational difficulty to derive the private key from the public key item. This comes from the difficulty of the underlying hard mathematical problem, such as integer factorization problem (*IFP*), discrete logarithm problem (*DLP*) (with best algorithms to solve them take subexponential time) and elliptic curve discrete logarithm problem (*ECDLP*) (with best algorithms to solve it take fully exponential time). The most popular systems of the public key cryptosystems are *RSA* (Rivest et al., 1978) which is based on the *IFP*, *ElGamal* cryptosystem (ElGamal, 1985) which based on the *DLP* and elliptic curve cryptosystem (*ECC*) (Miller, 1986; Koblitz, 1987) which is based on the *ECDLP*. For more details of this systems, we will introduce a brief discussion of the *RSA* and *ElGamal* cryptosystems.

Rivest et al. (1978) proposed the first practical public key cryptosystem, which is the *RSA* cryptosystem. This system is based on the difficulty of factoring a large number into two primes. Assuming that *Alice* and *Bob* are two users who want to communicate using an *RSA* cryptosystem. The *RSA* processing is as follows:

$$\begin{aligned} C &\equiv M^e \pmod{N} \\ M &\equiv C^d \pmod{N} \end{aligned} \quad (1.9)$$

where

- $M$  is the plain text.
- $C$  is the cipher text.
- $N = pq$ , with  $p \neq q$  large primes.
- $e$  and  $d$  are the public and private keys respectively, with  $\gcd(e, \phi(N)) = 1$  ( $\phi(N)$  is the Euler's function).

The pair  $(N, e)$  will be the public item and  $d$  should be kept as a private key. Now, if *Alice* wants to send a message  $M$  to *Bob*, she will use *Bob's* public key  $e$  and send  $C$ . *Bob* will use his own key  $d$  to decrypt  $C$  to the original message  $M$ . The proof of correctness of the *RSA* processing is as follows:

From assumption we have  $\gcd(e, \phi(N)) = 1$ , then  $de \equiv 1 \pmod{\phi(N)}$ . Then, there exists  $t \in \mathbb{Z}$  such that  $ed = t\phi(N) + 1$ . Now,

$$C^d \pmod{N} \equiv (M^e)^d \pmod{N}$$

$$\begin{aligned} &\equiv M^{t\phi(N)+1}(\text{mod } N) \\ &\equiv (M^{\phi(N)})^t M(\text{mod } N) \end{aligned}$$

Since  $M < N$  and  $N = pq$ , then  $\gcd(M, N) = 1$ . Now, using Euler's theorem (Yan, 2002) "If  $\gcd(a, n) = 1$  for any two positive numbers  $a$  and  $n$ , then  $a^{\phi(n)} \equiv 1(\text{mod } n)$ ". As a result  $C^d(\text{mod } N) \equiv M(\text{mod } N)$ .

The underlying hard mathematical problem for security in the *RSA* cryptosystem is to find the factors  $p$  and  $q$  from  $N$ . Factoring a number of size 1024 bits is well beyond the capability of the best current factoring algorithms (Stinson, 2006).

ElGamal (1985) proposed *ElGamal* public key cryptosystem, which is based on *DLP*. Assuming that *Alice* and *Bob* are two users who want to communicate using an *ElGamal* cryptosystem. The *ElGamal* processing is simply as follows:

$$C_1 \equiv g^k(\text{mod } p) \quad (1.10)$$

$$C_2 \equiv Me^k(\text{mod } p) \quad (1.11)$$

$$M \equiv (C_1^d)^{-1}C_2(\text{mod } p) \quad (1.12)$$

where

- $M$  is the plain text.
- $C_1$  and  $C_2$  are the cipher texts.
- $g$  is the primitive root of  $F_p$ .
- $e$  is the public key.
- $k$  and  $d$  are private keys.

$e \equiv g^d(\text{mod } p)$  is the public key and  $d$  should be kept as a private key. Now, if *Bob* wants to send a message  $M$  to *Alice*, he will use his chosen key  $k$  such that  $1 \leq k \leq p - 1$ , and the public key  $e$  to send the pair  $C_1, C_2$ . *Alice* will decrypt  $(C_1, C_2)$  to  $M$  by using her own key  $d$ . The proof of correctness of the *ElGamal* processing is as follows:

$$\begin{aligned} M &\equiv (C_1^d)^{-1}C_2(\text{mod } p) \\ &\equiv ((g^k)^d)^{-1}Me^k(\text{mod } p) \\ &\equiv (g^{dk})^{-1}M(g^d)^k(\text{mod } p) \end{aligned}$$

$$\equiv M(\text{mod } p)$$

The underlying hard mathematical problem for security in the *ElGamal* cryptosystem is to find the  $x$  such that  $g^x \equiv h(\text{mod } p)$  where  $g$  is the primitive root of  $F_p$ . The digital signature algorithm (*DSA*) (Locke and Gallagher, 2009) and *DHKE* are other systems based on the difficulty of solving *DLP*.

In particular, *DLP* can be applied on the group of points on an elliptic curve over finite field, to be *ECDLP*. That is, to find the integer  $k$ ,  $1 \leq k \leq n - 1$ , given  $Q = kP$ ,  $P$  a point on the elliptic curve over finite field, and  $P$  of order  $n$ . *ECDLP* is the underlying hard mathematical problem for the security in the *ECC* (Koblitz et al., 2000). Since there is no known subexponential algorithm to solve the *ECDLP* (Koblitz et al., 2000; Hankerson et al., 2004), then the *ECC* with smaller key size and less memory, offers the same level of security as the other public key cryptosystems.

In the mid 1980s, Miller (1986) and Koblitz (1987) opened the door for application of elliptic curve in cryptography. Nowadays, *ECC* is considered a good public key cryptosystem for low memory devices such as smart cards and phones since smaller bit sizes are used for operations. In Chapter 2, we will discuss the preliminaries of elliptic curve arithmetic. More specifically, we will introduce elliptic curve analogue of *DHKE*, *ElGamal* and *DSA* systems.

## 1.2 Problem Statement

*ECC* has become widely accepted and standardized as the public key cryptosystem due to its ability to provide the same level of security as the other public key cryptosystems, while using far smaller key sizes. For example, *ECC* requirement for obtaining an acceptable security level is 163 bits, while it is 1024 bits for *RSA* (Xiao et al., 2011). Table 1.1 provides other examples of the superiority of the *ECC* over not only the *RSA*, but even the *DSA* in terms of security level (Sandeep and Shanavas, 2012; N.Thangarasu, 2014).

| Table 1.1: Security Level of <i>ECC</i> |                |            |                |
|-----------------------------------------|----------------|------------|----------------|
| Time Braking in <i>MIPS</i> Years       | Key Size       |            | Key Size Ratio |
|                                         | <i>RSA/DSA</i> | <i>ECC</i> |                |
| $10^4$                                  | 512            | 106        | 5 : 1          |
| $10^8$                                  | 768            | 132        | 6 : 1          |
| $10^{11}$                               | 1024           | 163        | 7 : 1          |
| $10^{20}$                               | 2043           | 210        | 10 : 1         |
| $10^{78}$                               | 21000          | 600        | 35 : 1         |

The operation  $kP$  is involved in the *ECDLP*. Since *ECC* depends on the difficulty of solving the *ECDLP*, then the computational performance of *ECC* depends of the efficiency of the  $kP$  operation.  $kP$  is the elliptic curve scalar multiplication (*ECSM*) (also known as an elliptic curve point multiplication). *ECSM* is the operation of computing an integer multiple of an element in the group of elliptic curve. In other words, this operation is exactly the processing of computing  $Q$  as follows:

$$Q = kP = \underbrace{P + P + \dots + P}_{k \text{ times}} \quad (1.13)$$

where  $k$  is a positive integer called scalar and  $P$ ,  $Q$  are elliptic curve points.  $P$  and  $Q$  are considered as public keys, while the scalar  $k$  is considered as a private key. As mentioned earlier, given  $P$  and  $Q$ , it is computationally hard to calculate the scalar  $k$ . Therefore, reducing the number of these additions ( $k \text{ times}$ ) will make the *ECSM* faster, and then it will make *ECC* more efficient. Another reason for considering the *ECSM* as the most important part of *ECC* is the involvement of this operation in the key generation, key exchange, encryption, and decryption processing and even in the elliptic curve digital signature algorithm (*ECDSA*) (Johnson et al., 2001). There are multiple investigations on how to make this operation over prime or binary fields faster as much as possible.

The structure of the *ECSM* operation involves three computational levels: field arithmetic, point arithmetic and scalar arithmetic (Hankerson et al., 2004). In this work, the focus is on developments at the elliptic

curve point arithmetic and scalar arithmetic levels of elliptic curves over prime field.

The computation of the elliptic curve point arithmetic involves the effective implementation of point doubling and point addition operations. An elliptic curve can be represented using several coordinates systems. For each such system, the speed of point doubling and point addition operations is different. This means a good choice of coordinates system is an important factor for speeding up the *ECSM*.

In the scalar arithmetic level, efforts have been mainly focused on developing efficient algorithms for representation of the scalar  $k$  that reduces the number of operations required for the computation of the *ECSM*. The basic technique to compute the *ECSM*  $kP$  is based on the binary form of the scalar  $k$  which is called the binary method (Knuth, 1997), the non adjacent form (*NAF*) (Booth, 1951) and window  $w$ -non adjacent ( $w - NAF$ ) (Cohen et al., 2010) are efficient methods to compute  $kP$ .

### 1.3 Objectives

The objective of this study is to improve the performance of the *ECSM* operation for elliptic curve over prime field. The structure of the *ECSM* operation involves three computational levels: field arithmetic, point arithmetic and scalar arithmetic. In this work, the focus is on developments at the elliptic curve point arithmetic and scalar arithmetic levels of elliptic curves over prime field. The intention is to achieve this objective by accomplishing the following items:

1. To look for efficient point doubling and point addition operations using minimum cost and less complexity. To achieve this objective, methods employed to compute the elliptic curve scalar multiplication by introducing a new coordinate system in 4 dimension.
2. To look for scalar representation with minimal hamming weight or shorter bit length, To achieve this objective, it is proposed to use methods to compute the elliptic curve scalar multiplication operation by reducing the number of operations in the scalar. This will be by employing the *NAF* and  $w - NAF$  to represent the scalar by using the addition operation.
3. To look for scalar representation with minimal hamming weight or shorter bit length. To achieve this objective, it is proposed to use

methods based on *DRM* algorithm.

## 1.4 Thesis Organization

This thesis is a study of the *ECSM* operation and discusses theoretical and practical aspects of this operation. It is organized as follows:

- In this Chapter 1 we have provided a background on cryptology and explained the original of the various related cryptology terms used in this study, followed by the Problem Statement. The Private and Public Key Cryptosystems are then discussed., followed by the Study Objectives which are defined.
- Chapter 2 introduces the basic concepts of the mathematical background needed to understand computational aspects of elliptic curves relevant to their use in cryptography. Starting from the abstract algebra of groups and finite fields to the arithmetic concepts that form the computation of the *ECSM*, this is followed by the underlying hard problem for security in the *ECC*, and the examples for *ECC* such as curve analogue of *DHKE*, *ElGamal* and *DSA* systems.
- In Chapter 3, this thesis briefly surveys the algorithms known for computing the *ECSM* operation with a discussion of how we can develop. All methods mentioned (except the binary method) will form the basis for speeding up the *ECSM* operation in Chapters Five and Six. It starts with an introduction on *ECSM* describing the mathematical levels involved in its structure. And then, some basic definitions are listed when the cost of computing the *ECSM* operation is discussed.
- Chapter 4 introduces a modification on Jacobian coordinates, which give faster *ECDBL* and *ECADD* operations than affine, projective, and Jacobian coordinates systems. Each point on the elliptic curve over prime field is present by the 4– dimensional coordinates  $(X = xT, Y = yZ^3, Z, T = Z^2)$  corresponding to the affine point on the same curve  $y^2 = x^3 + ax + b$  over  $F_p$ . The basis of this technique is to rewrite the *ECDBL* and *ECADD* operations with less costly field multiplication inversion, multiplication and squaring operation.

- Chapter 5 comprised the introduction of two methods to enhance the computation of the *ECSM* operation:
  - First proposed method is to compute the *ECSM* operation. This algorithm will give a guarantee that it is one of the methods that accelerate the *ECSM* operation on *ECC*. The *NAF* is used to represent the scalar in *ECSM*, which will reduce the cost of computation of the *ECSM* operation.
  - The second proposed method is to compute the *ECSM* operation. This algorithm will guarantee that it is one of the methods that accelerate this operation on *ECC*. The  $\omega - \text{NAF}$  will be used to represent the scalar in *ECSM*, which will reduce the cost of computation of the *ECSM* operation. Furthermore, it will be proven that the form coming in this proposed method with its condition exists.
- In Chapter 6, we will introduce other algorithms (third and fourth) to compute the *ECSM* ( $kP$ ) operation using the *DRM* technique but with the lowest number of non zero bits of the scalar  $k$  compared with existing algorithms to compute *ECSM* operation.
  - The third proposed method will be based on the *DRM* technique and binary form for the scalar  $k$ .
  - The fourth proposed method will be based on the *DRM* technique and *NAF* for the scalar  $k$ .
- Chapter 7 will provide a conclusion and recommendations for related future research.
- Finally, in Appendix A we will list all programs which used the computations of this study. All these programs are written in *Intel(R)Core(TM)2Duo* with processor 2.99GHz and 3.00GB of memory using *MATLAB* version 7.10.0.499 (R2010a).
