Faculty : Science

The development of chiral electrochemical sensor in the recognition of Penicillamine (Pen) enantiomer is important for the production of pure enantiomers over racemate in the treatment of an array of diseases. The preparation of the modified electrode was a twofold procedure in which electrodeposition of ZnO was conducted first on the ITO glass substrate. The optimum deposition parameters were at -0.9 V, in a buffer solution of pH 7 at 60 °C for 900 s based on the cyclic voltammetry (CV) data obtained. The second part of the procedure involved dropcasting Van solution on the surface of the ZnO/ITO modified electrode. Electrochemical impedance spectroscopy (EIS) were carried out to characterize the electrical conductivity of the modified electrodes.. In this study, a novel chiral electrochemical sensor based on ZnO/vancomycin modified indium tin oxide glass substrate (ZnO/Van/ITO) was successfully fabricated and used in the chiral recognition of Pen enantiomers. The results showed that the charge transfer resistance (R_{CT}) is the greatest for ZnO/Van/ITO followed by ZnO/ITO, Van/ITO and bare ITO. Field Emission Scanning Electron Microscopy was carried out to study the surface morphology of the modified electrodes surface.

Different oxidation peak current, I_p of L- and D- Pen were observed in the differential pulse voltammograms (DPV) obtained in the solution containing L- or D-Pen. Under optimum condition, the chiral sensor exhibited good linear response to Pen enantiomers in a linear range of 5 mM to 30 mM with a detection limit of 23.56 mM and 14.73 mM (S/N=3) for the D-Pen and L-Pen respectively. This proposed electrode was shown to exhibit excellent performance in terms of low detection limit and good enantioselectivity for Pen enantiomers. Molecular docking using PyRx was further used to study the computational binding effect of the Van and Pen enantiomers. The

results showed that the binding effect was more prevalent for D-Pen as compared to L-Pen with a value of -2.3 kcal/mol and -2.4 kcal/mol for the D-Pen and L-Pen respectively. The association constant from the experiment, K_D and K_L obtained were 2.314×10^3 and 1.076×10^3 L/mol for the D and L-Pen respectively. The value of K_D was larger compared to K_L indicating that the binding effect is higher between Van/ZnO with D-Pen. The results obtained suggested that this chiral sensor has the ability to discriminate chiral drugs which is useful in pharmaceutical industries.

Abstrak tesis yang dikemukakan kepada Senat Universiti Putra Malaysia sebagai memenuhi keperluan untuk ijazah Master Sains

**PEMENDAPAN PERMUKAAN ZINK OKSIDA/ VANKOMISIN BAGI
PENGESANAN ELEKTROKIMIA ENANTIOPILIHAN BAGI
ENANTIOMER PENISILAMINA**

Penciptaan sebuah sensor elektrokimia kiral dalam pengesanan enantiomer Penisilamina adalah penting dalam pengeluaran enantiomer asli berbanding racemate dalam merawat pelbagai penyakit. Penyediaan elektrod yang diubahsuai adalah menggunakan dua prosedur. Pertama, elektrodposisi ZnO dijalankan terlebih dahulu pada substrat kaca ITO. Parameter optimum adalah pada -0.9 V, dalam larutan elektrolit pH 7 pada 60 °C selama 900 s berdasarkan data voltametri kitaran (CV) yang diperolehi. Bahagian kedua prosedur tersebut melibatkan titik tuang Van pada permukaan ZnO/ITO untuk mengubah elektrod tersebut. Pengesan novel elektrokimia kiral menggunakan substrat kaca indium tin oksida (ITO) yang diubahsuai dengan zink oksida dan vankomisin (ZnO / Van / ITO) berjaya direka dan digunakan dalam pengesanan kiral enantiomer penisilamina (Pen). Spektroskopi impedans elektrokimia (EIS) telah dijalankan untuk mengkaji kekonduksian elektrik elektrod yang diubahsuai. Keputusan menunjukkan bahawa rintangan pemindahan caj (R_{CT}) adalah yang paling besar untuk ZnO / Van/ITO diikuti oleh ZnO/ITO, Van/ITO dan ITO. Mikroskopi Elektron Penskanan Pelepasan Medan (FESEM) telah dijalankan untuk mengkaji morfologi permukaan permukaan elektrod yang diubahsuai.

Arus puncak pengoksidaan L-dan D-Pen yang berlainan, I_p , dapat diperhatikan dalam voltamogram pulsa (DPV) yang diperolehi dalam elektrolit yang mengandungi L- atau D-Pen. Dalam keadaan optimum, sensor kiral mempamerkan tindak balas linear yang baik untuk enantiomer Pen dalam julat linear 5 mM hingga 30 mM dengan had pengesanan 23.56 mM dan 14.73 mM ($S / N = 3$) untuk D-Pen dan L-Pen. Elektrod yang dibina ini menunjukkan prestasi cemerlang dari segi had pengesanan yang rendah dan enantiopilihan yang baik untuk enantiomer Pen. Pengedokan molekular menggunakan perisian PyRx digunakan untuk mengkaji kesan pengikatan komputasi

Van dan enantiomer Pen. Hasilnya menunjukkan bahawa kesan pengikatnya lebih tinggi bagi D-Pen berbanding L-Pen dengan nilai -2.3 kcal / mol dan -2.4 kcal / mol untuk D-Pen dan L-Pen. Pemalar penyekutuan dari eksperimen, K_D dan K_L yang diperolehi masing-masing adalah 2.314×10^3 dan $1.076 \times 10^3 \text{ L / mol}$ untuk D dan L-Pen. Nilai K_D lebih besar berbanding K_L menunjukkan bahawa kesan mengikat lebih tinggi antara Van/ZnO dengan D-Pen. Keputusan yang diperolehi mencadangkan bahawa sensor kiral ini mempunyai keupayaan untuk membezakan molekul kiral yang boleh menyumbang dalam industri farmaseutikal.

ACKNOWLEDGEMENTS

My undying gratitude goes to Dr Ruzniza Zawawi, for I am only able to complete this study through her continuous supervision and support. The knowledge I have gained from her would no doubt be invaluable to me throughout my academic and working life. I am also grateful to my co-supervisors, Prof. Dr. Zulkarnain Zainal, and Dr. Ernee Noryana Muhamad for their valuable advices and guidances rendered for the completion of this thesis.

I am greatly indebted to Miss Bavani, and Miss Aini, for their assistance in my various lab analysis. They also aided me greatly by showing my errors in the entire duration of my study. I have to also thank Dr. Alif for assisting me in the molecular docking workings. My sincerest gratitude goes to Dr Moniza Waheed from the Department of Communication for her constant reminder to me on life goals. Not to forget, Mr Keeren for the good times after 8 years of friendship.

I also would like to take this opportunity to thank Associate Professor Dr. Arifin Abdu, Principal of 13th College, and Mr Nazarudin Ramli, Manager of 13th College for allowing me use the facilities in the college when I am stressed up with my work. Not to forget, 13th College fellows, Said, Aiza, Zira and Khairy.

Finally I would like to thank my father, Dr. Lim Khong Chiu, my siblings, Dr. Eric Lim Teik Chung, Dr. Felicia Lim Chun Min and Andy Lim Teik Hong for their enduring support and everlasting love. I would also like to dedicate this thesis to the most important person in my life, Ng Yoke Oi, my mother for always being there for me, to praise me during my times of glory and to comfort me during my times of failure. There are no words to describe my appreciation for her and I hope the completion of this study would serve as a symbol of my appreciation

I certify that a Thesis Examination Committee has met on 26 January 2018 to conduct the final examination of Alvin Lim Teik Zheng on his thesis entitled "Surface Deposition of Zinc Oxide/Vancomycin for Enantioselective Electrochemical Sensing of Penicillamine Enantiomers" in accordance with the Universities and University Colleges Act 1971 and the Constitution of the Universiti Putra Malaysia [P.U.(A) 106] 15 March 1998. The Committee recommends that the student be awarded the Master of Science.

Members of the Thesis Examination Committee were as follows:

Shahrul Ainliah binti Alang Ahmad, PhD

Senior Lecturer
Faculty of Science
Universiti Putra Malaysia
(Chairman)

Mansor bin Hj Ahmad @ Ayob, PhD

Professor
Faculty of Science
Universiti Putra Malaysia
(Internal Examiner)

Sharifah Mohamad, PhD

Associate Professor
University of Malaya
Malaysia
(External Examiner)

NOR AINI AB. SHUKOR, PhD
Professor and Deputy Dean
School of Graduate Studies
Universiti Putra Malaysia

Date: 26 April 2018

This thesis was submitted to the Senate of the Universiti Putra Malaysia and has been accepted as fulfilment of the requirement for the degree of Master of Science. The members of the Supervisory Committee were as follows:

Ruzniza Zawawi, PhD

Senior Lecturer
Faculty of Science
Universiti Putra Malaysia
(Chairman)

Zulkarnain Zainal, PhD

Professor
Faculty of Science
Universiti Putra Malaysia
(Member)

Ernee Noryana Muhamad, PhD

Senior Lecturer

CHAPTER 1

INTRODUCTION

1.1 General background

The recognition of chiral molecules has been a well-studied subject matter due to their importance to human mankind. It is well known that enantiomers exhibit differing properties in terms of its toxicology, pharmacology and pharmacodynamics even though they possess almost similar molecular structure. The medical and pharmaceutical industries would require pure enantiomer over the racemate in the production of medicines and effective treatments. Chiral recognition and separation of racemic drugs has been an interesting research subject since the introduction of the racemic switch strategy adapted by pharmaceutical industries (Nguyen *et al.*, 2006). Upon comparing affinities, enantiomer exhibiting higher affinity or higher activity is called 'eutomer' while the lower affinity or lesser activity is called 'distomer' (Burke and Henderson, 2002).

There are two known methods in the process of resolving enantiomers which are direct and indirect chiral separation. The indirect chiral separation utilizes derivatization of enantiomers into diastereomers applying optically pure reagent. The process is conducted in this manner as diastereomers differ in their chemical properties in which they can be separated in an achiral environment (Blanco and Valverde, 2003). However, for direct chiral separation method, it is based on labile diastereomers formation with the presence of chiral selector. To date, there are several techniques utilised in chiral analysis, the commonly employed methods are such as spectroscopic methods, high-performance liquid chromatography (HPLC), and electrochemical methods. However, electrochemical methods can be advantageous compared to other techniques due to its simplicity, accuracy, and low material cost. In order to increase sensitivity and selectivity of electrochemical measurements, the implementation of nanomaterials with high surface area and good electrical conductivity such as carbon nanomaterial and metal nanoparticles have been introduced on the surface of the electrode.

Enantioselective sensors have been an effective tool in the monitoring of different interactions of enantiomers, determining purity in chirally pure marketed products and studying toxicological effects of enantiomer. Chiral analysis can be considered a rapidly profound research in the past decade due to its importance in various fields, notably, pharmaceutical and clinical applications due to the potential of different activities and toxicities of drug enantiomers. There are several techniques utilized in chiral analysis, the most common is via spectroscopy methods, high-performance liquid chromatography, and electrochemical methods. The concept of chirality can also been studied in the application of biosensors.

To date, many chiral recognition sensors have been developed that shown to have high sensitivity, selectivity, and compatibility in biological assay. The principal objective of chiral recognition is to construct an effectual chiral selective system, which should have recognition sites for certain chiral enantiomers (Guo *et al.*, 2009). The choice of chiral selector is indeed important to achieve the desired results in chiral analysis. The usage of macrocyclic antibiotics such as glycopeptide, polypeotide and ansamycins as an effective chiral selector reveals a very steady growth of its usage in chiral discrimination of enantiomers (Claudia and Salvatore, 1998).

1.2 Problem Statement

In the current age, the medical and pharmaceutical industries is thriving and require fast and reliable analysis on chiral drugs in which they require pure enantiomer over the racemate in the production of medicines and effective treatments. Nowadays, the commonly used technique in the discrimination of chiral molecules is time consuming and high cost. Electrochemical method has garner wide interest as a reliable technique in chiral analysis. The important research questions that arise revolves around one very important aspect; whether electrochemical determination using vancomycin as the chiral selector of the enantiomer pairs can be a reliable alternative that can provide a substantial data on the discrimination of penicillamine enantiomers.

In this study, the chiral selector employed is vancomycin which is a macrocyclic glycopetide that is proven to successfully discriminate enantiomers in many techniques such as high-performance liquid chromatography (HPLC) and electrochemical methods. The interesting properties of vancomycin containing an array of chiral centre containing functional groups that interacts with the analyte is worth to be explored. Although ZnO is known to be a poor electrochemical compound, it is hoped to understand the capability of ZnO in biosensing capability upon reacting with a macrocyclic glycopeptide for the discrimination of chiral molecules. Since, ZnO is known to exhibit various desirable traits for biosensing such as high catalytic efficiency, strong adsorption capability, and high isoelectric point (IEP; ~9.5) which are suitable for adsorption of certain proteins (e.g. enzymes and antibodies with low IEPs) by electrostatic interaction. Combining the unique properties of Van with ZnO as a hybrid couple is expected to enhance the chiral detection of the enantiomers. To date, there are no published report on the usage of ZnO/Van modified ITO in the chiral analysis of Penicillamine enantiomers. Hence the main goal of the present study was to develop a newly modified electrode based on ZnO/Van/ITO.

The simple experimental design of the nanohybrid electrode is hoped to be a reference for the development of chiral sensor. This will thus give important implications for biosensing, asymmetric syntheses and separation, and understanding the nature of chiral interactions in biological systems. The outcome could hold good application in the fields of electroanalytical chemistry and biosensors. Answers to these puzzling questions will bring significant impact on the understanding of the processes involving chiral molecules in living organism.

1.3 Objectives

The objectives of this study are:

- i. To grow the ZnO nanomaterials with well-controlled orientation via electrodeposition technique.
- ii. To optimize and characterize the properties of chiral surface composed of ZnO/vancomycin nanohybrid material suitable for enantioselective detection of D- and L- Penicillamine
- iii. To evaluate the capability of the prepared nanohybrid-modified electrode in the enantioselective electrochemical sensing of penicillamine enantiomers
- iv. To identify the mechanism of the enantioselective electrochemical sensing of penicillamine enantiomers by the nanohybrid matrix using computational method.
