DEDICATION

My Dear Family:

Mat Din Bin Derani

HasnahBinti Mat Zain

MuhamadHafizi Bin Mat Din

MuhamadHaqimi Bin Mat Din

To all my friends,

Nor Farah Wahidah Abdul Aziz

MuhamadWafiuddinRamlee

Thank you for your encouragements supports

And the sacrifices that you have given.

Thank you for everything. May Allah Bless All of us.

ABSTRACT

Sediment have a potential in storing carbon gases from the atmosphere and plays an important role in carbon cycle at mangrove ecosystem. In mangrove ecosystem sediments were found abundantly in the river brink. Therefore, to prove this statement, the study of carbon storage in the sediment was carried out at Sungai Tinggi in Matang Mangrove Forest, Perak. The objectives of this study are to provide a fundamental information of sediment carbon stored and to compare the carbon storage potential among three different zones and five different depths. One transect line was established along the river and divided into three zones (Upstream, Middle stream, Downstream). A total of 75 sediment samples were collected using peat auger in five different depths (0-15 cm, 15-30 cm, 30-50 cm, 50-100 cm, >100 cm). The standard method was used in sediment preparation and laboratory analysis. The obtained data was analyzed using SAS 9.2 to find mean comparison between zones and depths. As a result, middle stream with $10.819^a (\pm 0.234)$ % was obtained the highest content of total organic carbon compare to the other zones and shows significant different. In term of sediment depth, total organic carbon percentage was highest in depth five (>100 cm) with $12.528^a (\pm 0.281)$ %. As a conclusion, sediment is one of the potential for carbons stored but more research are need to be done to prove that the total organic carbon percentage are encourage by mangrove zones and depths.

ABSTRAK

Sedimen mempunyai potensi untuk menyimpan gas karbondioksida dari atmosfer dan memainkan peranan penting dalam kitaran karbon di ekosistem bakau. Dalam sedimen ekosistem bakau didapatkan banyak di persisiran sungai. Oleh itu, untuk membuktikan kenyataan ini, kajian penyimpanan karbon dalam sedimen telah dijalankan di Sungai Tinggi di Hutan Paya Laut Matang, Perak. Objektif kajian ini adalah untuk menyediakan maklumat tentang karbon sedimen disimpan dan untuk membandingkan potensi penyimpanan karbon di antar tiga zon yang berbeza dan lima kedalaman yang berbeza. Satu barisan set telah dibuat di sepanjang sungai dan dibahagikan kepada tiga zon (Hulu, aliran Tengah, Hiliran). Sebanyak 75 sampel sedimen telah dikumpulkan menggunakan gerimit gambut di lima kedalaman yang berbeza (0-15 cm, 15-30 cm, 30-50 cm, 50-100 cm, > 100 cm). Kaedah standard telah digunakan dalam penyediaan sedimen dan analisis makmal. Data yang diperolehi dianalisis menggunakan SAS 9.2 untuk mencari perbandingan antar zon dan kedalaman. Keputusannya, aliran pertengahan dengan 10.819^a (± 0.234)% didapatkan kandungan tertinggi daripada jumlah karbon organik berbanding dengan zon lain dan menunjukkan perbezaan yang signifikan. Dari segi kedalaman sedimen, jumlah peratus karbon organik adalah paling tinggi pada kedalaman lima (> 100 cm) dengan 12.528^a (± 0.281)%. Kesimpulannya, sedimen merupakan salah satu potensi untuk karbon disimpan tetapi lebih banyak penyelidikan perlu dilakukan untuk membuktikan bahawa jumlah peratus karbon organik dipengaruhi oleh zon bakau dan kedalaman.

ACKNOWLEDGEMENT

Thanks to Allah S.W.Tfor giving me the strength to carry on my study. I would not be able to finish my final year project which entitle “Sediment Carbon Storage of Mangrove Forest at Sungai Tinggi, Perak”.

I would like to acknowledge my supervisor, Assoc.Prof. Dr. SecaGandaseca from Faculty of Forestry, Universiti Putra Malaysia for his valuable advice, guidance, criticism and the time spent in teaching me throughout the preparation of this research.I also want to dedicate my appreciation to my advisors in this research, Mr. Ahmad Mustapha MohamadPaziand Mr. AhmadHanafiHamzah. Thank you for the valuable advice and assistance given throughout my research on this topic. Also, thank you to all member that involve directly or indirectly in the time spent in completing my research.

Last but not least, I want to thank my family for their endless support, understanding, and constant encouragement throughout the study.

APPROVAL SHEET

I certify that this research project report entitle “Sediment Carbon Storage of Mangrove Forest at Sungai Tinggi, Perak” by MuhamadHuzwa Bin Mat Dinhas been examined and approved as a partial fulfillment of the requirement for the degree of Bachelor of Forestry Science in the Faculty of Forestry, Universiti Putra Malaysia.

Approved by:

Associate Professor Dr. SecaGandaseca
Faculty of Forestry
Universiti Putra Malaysia
(Supervisor)

Prof. Dr. Mohamed ZakariaHussin
Dean

CHAPTER 1

INTRODUCTION

1.1 General Background

Mangrove forests are a salt-tolerant forest ecosystem found in the intertidal region of sheltered coastlines (Hamilton & Snedaker, 1984). Mangrove forests, also known as mangal, in the tropical regions, are commonly found at tidal areas such as estuaries (Ellison, 1999). Mangroves exist at the interface between land and sea in subtropical and tropical latitudes. Plants can grow well because of the low wave energy and mangroves work as a shelter that enable the deposition of sediment (Daniel, 2009). Worldwide, mangrove forests are found in the tropical and subtropical region. In Malaysia, mangrove forests can be found in areas located along sheltered coastlines protected from strong waves and cover an area of approximately 641,172 ha (Erinet al., 2010).

Mangroves have a lot of important roles such as protecting and maintaining the coastal water quality, reducing the impact of the wave and flood damage and also acting as a nursery and feeding area for commercial and artisanal fishery species (Kuenzer & Gebhardt, 2011). Not only that, mangroves also play crucial roles in global carbon cycling since they hold a large pool of carbon and serve as the potential carbon sinks and sources to the atmosphere. Sediment is a mixture of loose sand, clay, silt and other soil particles which usually exist in the lower part of the marine environment. Ongley (1996) stated that sediments play an important role in elemental cycling in the aquatic environment because they transport nutrients and also

contaminant. Soil erosion and decomposition of plants and animals are the source of sediment.

Sediment play an important role in marine environment as it carrying nutrient. However, it can leave negative impact to the forest when the water transport too much sediment because not only nutrient, but it also carried contaminant such as acid and metal that can damage the ecosystem. This phenomena was called unnatural sedimentation. Unnatural sedimentation typically comes from construction site and agricultural runoff (Chou et al., 2010). Ellison (1999) stressed that human disturbance produced a lot of sedimentation that causing problem to mangrove. Sedimentation may also become harmful when the root of mangrove tree are being buried. When this happen, there is less gasses exchange between roots and water. Thus, lessening the ability of the trees to respire and preventing an important physiological process. Chou et al. (1999) claim that excessive of sedimentation can prevents the light from reaching the mangrove root.

Other than that, mangrove forest will be harmed if the sedimentation impedes the tidal system on which they depend for vital nutrient. If there is no tide bringing in nutrient and get rid of the harmful excessive sediment, the health of mangrove forest will decrease. Ellison (2000) found that planting mangrove in an area with hampered tidal system will not be successful because they are dependent upon tidal flow to survive. Sedimentation affects all organisms differently. It can greatly changes the ecosystem by killing some of the native species. According to Chou et al. (2010) sediment often

results in the introduction of invasive species that are able to flourish in the newly introduced environment. Furthermore, sedimentation also can kill the native species in an area entirely.

The worldwide carbon cycle can be characterized as one of the major biogeochemical cycle due to its part in managing the centralization of carbon dioxide. Climate change is caused by the increasing of carbon dioxide concentrations in the atmosphere. Since the forest and other agriculture play an important role in helping to reduce the availability of carbon dioxide in the atmosphere. Soil and vegetation such as woody plant and plant residue can store the carbon (Tisdale et al., 1995).

1.2 Problem Statement

Carbon dioxide is one of the greenhouse gases lead to the climate change. Climate change happen due to the increasing concentration of the carbon dioxide in the atmosphere. As the climate change happen, this is become a huge problem to earth and human's life and one of the factor that lead to this problem happen is the release of excessive carbon dioxide. However, mangrove forests have a big potential to decrease carbon dioxide from the atmosphere by sequestering the carbon dioxide gases and stored into the soil.

Therefore, this study has been conducted to identify the carbon storage of the sediment and to compare the carbon storage of the sediment

between different zonation which consist of upstream, middle stream and downstream in the mangrove forest river located at Sungai Tinggi, Kuala Trong. Thus, the study is carrying out to determine the carbon storage of the sediment at Sungai Tinggi River.

1.3 Objectives

The objectives of this research are:

- I. To identify the sediment carbon storage of mangrove forest at Sungai Tinggi.
- II. To compare the sediment carbon storage of mangrove forest between different zonations (Up Stream, Middle Stream and Down Stream) of the Sungai Tinggi.
