

Hydrous ferric oxide-magnetite-reduced graphene oxide nanocomposite for detection of arsenic using surface plasmon resonance

ABSTRACT

Surface plasmon resonance sensor coated with hydrous ferric oxide-magnetite-reduced ($\text{Fe}_2\text{H}_2\text{O}_4\text{-Fe}_3\text{O}_4\text{-rGO}$) graphene oxide nanocomposite film was demonstrated to detect two toxic heavy metals; Arsenic (III) [As(III)] and Arsenic (V) [As(V)] in aqueous solution. The proposed nanocomposite film exhibited successful absorption of As with enhanced sensitivity and selectivity. Resultantly, when tested with different concentrations of As(III) and As(V), (0.1-1.0 ppb) the sensor ranged linearly with sensitivity of $2.196^\circ\text{ppb}^{-1}$ and $0.960^\circ\text{ppb}^{-1}$, respectively, and achieved a detection limit as low as 0.1 ppb. These results validate the potential of $\text{Fe}_2\text{H}_2\text{O}_4\text{-Fe}_3\text{O}_4\text{-rGO}$ nanocomposite material for optical sensing applications in as detection.
