

Catharanthus roseus extract as bio-fungicide for controlling *Fusarium oxysporum* on selected vegetable seedlings

ABSTRACT

Catharanthus roseus extracts were studied to evaluate their potentials replacing chemical fungicide which give a bad impact on human health and cause environmental pollution problems. The samples of *C. roseus* were extracted with different extraction solvents including dichloromethane (DCM), acetone, ethanol, and methanol at 5, 10, 15 and 20 mg/mL concentrations. The solvents without the plant extract were used as the controls. After 6 days of incubation, the inhibition zone of the fungal pathogen on PDA media was measured. The extracts were significantly effective ($p \leq 0.05$) in limiting the antifungal activities. The DCM extract of *C. roseus* was the most effective against *Fusarium oxysporum* with 8.06 mm compared to acetone (0.055 mm), ethanol (0.15 mm), methanol (0.41 mm), and water (0.06 mm). Among of the concentrations, 20 mg/mL gave the best effect to control the fungal pathogen compared to 5, 10 and 15 mg/mL. The *C. roseus* extract was also effective in controlling *F. oxysporum* on the selected vegetable seedlings based on leaf number and disease suppression (%) results. However, without treated with the extract; mortality due to *F. oxysporum* increased. The *C. roseus* extract was effective and may to be developed as a bio-fungicide agent to control *F. oxysporum* in the field.
