This thesis is dedicated to my beloved mother, husband, son, daughter and my best friend. Thank you for all the prayers.

Abstract of thesis presented to the Senate of Universiti Putra Malaysia in fulfillment of the requirement for the degree of Doctor of Philosophy

### MULTIFACTOR APPROACH TO PRIORITIZE EVENT SEQUENCE TEST CASES

By

### JOHANNA BINTI AHMAD

December 2018

### Chairman : Salmi Baharom, PhD Faculty : Computer Science and Information Technology

Software testing consumes 40 to 70 percent of the development effort, time, and cost, especially for large software systems. Test Case Prioritization (TCP) is a method to prioritize and schedule test cases in order to run test cases of higher priority to minimize time, cost, and effort during the software testing phase. Numerous TCP techniques have been proposed with a variety of criteria and evaluation metrics. However, in the context of prioritizing the event sequences test cases, most researchers agree that testing the event sequences test cases is more complex than the single event test cases. Meanwhile, one of the most significant issues in TCP is how researchers handle the same priority value issues. Most researchers either applied the random technique or did not provide any information regarding the same priority value issues in their research. Due to that reason, this research proposed Multifactor Weighted Approach (MFWA) using six factors: complexity, redundancy, frequency, permutations, fault matrix, and distance to improve the existing TCP technique that used random technique to break the ties once the same priority value exists during the prioritization process. The aim of this research is to combine all six factors to produce a unique weight for each test case. The ordered suite will be based on the final test case weight. The test case that has the highest weight will be executed first compared to the others. The mutation testing approach is selected to compare and evaluate the random technique and MFWA technique. Both techniques will execute the same test suites and codes. The effectiveness of both techniques is measured in terms of the capability to detect faults using the Average Percentage Faults Detected (APFD). Meanwhile, the efficiency refers to how quickly each technique is capable of detecting faults by referring to the position of the test case that managed to kill all the live mutants. The Jaccard Distance approach was managed to solve same priority value by measuring the similarities of the data state value among test cases. The new ordering of test case after the implementation of Jaccard Distance approach has been proof can detect faults earlier than others based on the Fault Detection table. In fact, the

empirical results indicated that the MFWA technique is more effective and efficient than the random technique.

Abstrak tesis yang dikemukakan kepada Senat Universiti Putra Malaysia sebagai memenuhi keperluan untuk ijazah Doktor Falsafah

### PENDEKATAN PELBAGAI FAKTOR UNTUK MENGUTAMAKAN KES UJIAN BAGI RANGKAIAN ACARA

Oleh

#### JOHANNA BINTI AHMAD

Disember 2018

### Pengerusi : Salmi Baharom, PhD Fakulti : Sains Komputer dan Teknologi Maklumat

Pengujian perisian menggunakan 40 hingga 70 peratus daripada usaha pembangunan, masa dan kos, terutamanya untuk sistem perisian yang besar. Pengutamaan Kes Ujian (TCP) adalah kaedah untuk mengutamakan dan menjadualkan kes-kes ujian dalam usaha untuk menjalankan kes ujian yang berkeutamaan lebih tinggi bagi meminimumkan masa, kos, dan usaha semasa fasa ujian perisian. Banyak teknik TCP yang telah dicadangkan merangkumi pelbagai kriteria dan metrik penilaian. Walau bagaimanapun, dalam konteks mengutamakan siri acara kes ujian, kebanyakan penyelidik bersetuju bahawa menguji rangkaian acara kes ujian adalah lebih kompleks daripada menguji kes ujian secara tunggal. Sementara itu, salah satu isu yang paling penting dalam TCP adalah bagaimana penyelidik mengendalikan isu nilai keutamaan yang sama. Kebanyakan penyelidik menggunakan samada teknik rawak atau tidak memberikan sebarang maklumat mengenai isu nilai keutamaan yang sama dalam penyelidikan mereka. Disebabkan itu, penyelidikan ini mencadangkan Pendekatan Pelbagai Faktor Pemberat/Bebanan (MFWA) menggunakan enam faktor: kerumitan, lebihan, kekerapan, penggantian/pilihatur, kesalahan matrik dan jarak untuk memperbaiki teknik TCP yang sedia ada yang menggunakan teknik rawak untuk memecahkan ikatan sejurus nilai keutamaan yang sama wujud semasa proses pengutamaan. Tujuan penyelidikan ini adalah untuk menggabungkan semua keenamenam faktor untuk menghasilkan beban unik untuk setiap kes ujian. Set yang dipesan akan berdasarkan bebanan kes ujian akhir. Kes ujian yang mempunyai bebanan tertinggi akan dilaksanakan terlebih dahulu berbanding yang lain. Pendekatan ujian mutasi dipilih untuk membandingkan dan menilai teknik rawak dan teknik MFWA. Kedua-dua teknik akan melaksanakan set ujian dan kod yang sama. Keberkesanan kedua-dua teknik diukur dari segi keupayaan untuk mengesan kesilapan menggunakan kaedah Peratusan Purata Kesalahan Dikesan (APFD). Sementara itu, kecekapan merujuk kepada seberapa cepat setiap teknik mampu mengesan kesilapan dengan merujuk kepada kedudukan kes ujian yang berjaya mematikan semua mutan hidup.

Pendekatan jarak jauh mampu menyelesaikan isu nilai keutamaan yang sama dengan cara mengukur kesamaan nilai keadaan data di kalangan kes ujian. Susunan baru kes ujian selepas pelaksanaan pendekatan jarak jauh telah terbukti dapat mengesan kesilapan lebih awal daripada yang lain berdasarkan jadual Pengesanan Kesilapan. Keputusan empirikal menunjukkan bahawa teknik MFWA lebih berkesan dan cekap daripada teknik rawak.

### ACKNOWLEDGEMENTS

I would like to express my sincere gratitude to my beloved supervisor, Dr. Salmi binti Baharom for her guidance, suggestions, support, and encouragement during the research process. I would also like to express my warm and sincere thanks to my cosupervisors, Professor Dr. Hj. Abdul Azim bin Abd Ghani, Associate Professor Dr. Hazura binti Zulzalil, and Dr. Jamilah binti Din for their invaluable guidance.

I would like to express my appreciation to my loving husband, Hasraf Azad, my mother, Isam, my son, Aiman Hakim, and my daughter, Adelia Akhtar. It would have been impossible for me to finish this study without their understanding and support. Not to forget my best friend, Adilah, for always supporting me whenever I face difficulties during my research, and of course, for praying for my success. Thank you all for the support and prayers throughout these years. May Allah (SWT) bless us all.

Finally, I would like to acknowledge every individual for his or her invaluable help, and cooperation throughout my research.

This thesis was submitted to the Senate of the Universiti Putra Malaysia and has been accepted as fulfillment of the requirement for the degree of Doctor of Philosophy. The members of the Supervisory Committee were as follows:

### Salmi Baharom, PhD

Senior Lecturer Faculty of Computer Science and Information Technology Universiti Putra Malaysia (Chairman)

### Abdul Azim Abd Ghani, PhD

Professor Faculty of Computer Science and Information Technology Universiti Putra Malaysia (Member)

### Hazura Zulzalil, PhD

Associate Professor Faculty of Computer Science and Information Technology Universiti Putra Malaysia (Member)

### Jamilah Din, PhD

Senior Lecturer Faculty of Computer Science and Information Technology Universiti Putra Malaysia (Member)

### **CHAPTER 1**

#### **INTRODUCTION**

Software testing is known as a crucial phase in software development life cycle. In general, the objective of software testing is to provide information about the quality of a product or service to the stakeholders or customers. Software testing involves the process of executing a programme with the intention of discovering as much error as possible in the estimated time. As the size of a system becomes larger, the complexity of the system will also increase. Hence, the significance of the testing phase will also increase due to its importance in revealing potential faults. As a result, some projects would perform exhaustive testing to ensure the quality of the system and to maintain the quality once changes or modifications are made. The exhaustive testing, however, requires for a great deal of cost, effort, and time.

In the last several decades, numerous techniques have been proposed in reducing the cost, effort, and time of the testing phase. Most software testing researches would discuss the issue on the generation of test cases. The research in software testing can be categorized into test case generation, test oracle generation, and test case execution. Test case generation is the most dominant test compared to test oracle generation and test case execution. Test case execution. Test case prioritization (TCP) is one of the techniques in test case generation that is used in reducing the time and cost of testing. TCP technique can be adopted either in the regression or non-regression testing.

### 1.1 Research Motivation

For a large commercial system, the test suites can contain thousands of test cases and may sometimes be infinite. The issue of the large number of test cases was reported by Rothermel et al. (1999), where one of the industrial collaborators reported that they had to run 200,000 lines of codes for seven weeks. Numerous techniques have been studied to cater the large number of test cases issues: test case minimization, test case selection, and TCP (Yoo & Harman, 2007). A number of TCP techniques have been proposed since 1997 to detect the defects as early as possible, aside from reducing time and cost (Silva Ouriques et al., 2015). With the TCP technique, the more important test case will be executed earlier (Yu & Lau, 2012).

 $\bigcirc$ 

The TCP technique is widely used for single-event test cases, however, only a few studies have focused on event sequence test cases (He & Bai, 2015; Huang et al., 2010; Bryce et al., 2011). This is because event sequences are difficult to handle, whereby there is a possibility of the test cases having a combination of events, with a large input sequence, as well as a large amount of test cases that have considerable degrees of redundancy (Huang et al., 2010; Bryce et al., 2011; Silva Ouriques et al., 2015). Harman (2007) addressed the complexity of testing event sequences due to the large test space, different positions of the events, and various permutations of inputs.

Generally, event sequence test cases have enormous numbers of states and every state should be tested. Changes in one internal data state to another should be taken under consideration since they involve interactions between events (Kumar, 2016).

Throughout the years a huge number of TCP techniques have been proposed with varieties of combinations factors to improve the effectiveness of the test case generation (Tonella et al., 2006; Huang et al., 2010; Jena et al., 2015; He & Bai, 2015; Ammar et al., 2016). However, some of these researches failed to prioritize multiple test suites and test cases with the same priority value (Huang et al., 2010; Ammar et al., 2016). The random technique will be applied once the same priority value exists during the prioritization process. Specifically, the existing works failed to cater to the same priority value for the event sequence test cases. In addition to the general limitations and gaps in prioritizing event sequence test cases as previously mentioned, it also shows that the TCP technique has not been extensively explored for this purpose.

The basic motivation behind the limitations and gaps that exist in the existing work is to produce a unique weight approach to avoid the random technique. This, consequently, can increase the effectiveness of the TCP technique. The random technique is ineffective and can create bias issues (Tonella et al., 2006; Ammar et al., 2016). Furthermore, the random technique can produce a large amount of testing data to be executed, which would result in the increase of time, effort, and cost during the testing phase, as well as causing some of the important test cases to be missed out for during testing.

The issues that exist in the previous TCP technique provide the fundamental motivation in improving the effectiveness and efficiency of the existing TCP technique. Therefore, the focus is on software testing, to determine whether the proposed approach is able to maintain and focus in terms of data testing, and its ability to detect faults earlier.

### **1.2 Problem Statement**

Prior to breakthroughs in 1997, people would randomly generate test cases and select the best test cases based on the results without knowing the quality of the test cases. For this reason, numerous TCP techniques have been proposed to prioritize test cases especially for the large commercial system. There are still a number of important issues neglected by previous researchers. To date, existing TCP technique prioritize the test cases in terms of the basic blocks, number of lines of codes, number of covered methods or execution history on a previous version (Sebastian Elbaum et al., 2004; Mirarab & Tahvildari, 2007; Zhang et al., 2013; Ammar et al., 2016). Some TCP techniques order the test case execution in accordance with their degree of importance, which is indirectly defined. A weighted approach was proposed as an effective predictor to select the best test case ordering (Sebastian Elbaum et al., 2014). A test case priority is based on the weight given to a test case during the prioritization process (Srivastava et al., 2009; Panichella et al., 2014). The weight of the test case depends on the prioritization algorithm. For example, if the algorithm is based on the number of executed statements, then any test case that has the highest number of executed statements will have higher priority than other test cases.

However, most researchers have reported that the proposed algorithms would end up with the random technique (Lin & Huang, 2009; Bryce et al., 2011). Random technique has been applied to break ties. In other word, break ties mean if more than one test case have the same priority value. Nonetheless, it has been proven as an ineffective choice because there is no guarantee that the chosen technique is the best compared to other choices (He & Bai, 2015; Ammar et al., 2016). The random technique may uncover faults that were missed during the development phase.

For example, a test suite consists of three test cases with different combinations of event sequences: for TC1, a combination of event C and event A; TC2 is a combination of event B, event C, and event A; while TC3 consists of combinations of event B, event A, and event A. Assume that the weight value of each event is as follows: event A = 1, event B = 2, event C = 3. Finally, the summation weight of TC1 is 4, TC2 is 6, and TC3 is 6. The weight values show that TC2 and TC3 have the same priority value. This leads to an important question, "Which test case should be executed earlier, TC2 or TC3?" The effectiveness and efficiency in detecting faults is not the same, even if the summation weight is equal (Huang et al., 2010). Therefore, this study is interested in answering this question by proposing an approach that produces a unique weight value for each test case during the prioritization process.

One of the most significant current discussions is in terms of the combination of factors that can influence the effectiveness and efficiency of the TCP technique (Srikanth & Cohen, 2011; Khalilian et al., 2012). Previous researchers believe that these factors are capable of improving the rate of failure detection, as well as the ability to solve the same priority value issue (Chaudhary et al., 2014; Fang et al., 2014; Frolin S. Ocariza et al., 2015). For example, if TC1 and TC2 have the same priority value for branch coverage, each test case has the possibility to exercise different coverage (Khalilian et al., 2012). Furthermore, there is no indicator to show the similarity or differences between test cases that have the same priority value.

Assume that the number of *if-else* conditions in TC1 is greater than in TC2. From the perspective of the complexity measurement theory, it is extremely doubtful to assume that both correspond to the same complexity measurement. Thus, an indicator that could detect between similarities and differences needs to be defined to cater to this issue. Ammar et al. (2016) found that whenever two or more test cases have equal weight, they would mostly cover the same segment of codes. Based on that finding,

they arranged the test cases using the initial orders. Hence, without strong justifications based on findings, as reported by Ammar et al. (2016), we cannot simply assume that all test cases with the same priority value cover the same faults during testing. However, the current issue that this study aims to address is how to define an indicator to prove that test cases with the same priority value have different fault coverage.

Based on the Systematic Literature Review (SLR) evaluation which has been conducted, most of the previous researchers either applied random technique or did not provide any information regarding the same priority value issues in their research. Out of 50 primary studies, 98 percent applied random technique in case if two or more test cases have same priority value during the prioritization process. Detail of the SLR analysis is in Appendix A. Those limitations been a burgeoning interest for this research to propose a unique weight approach to prioritize event sequences test cases.

### 1.3 Research Objectives

This research objectives that are addressed in this thesis are as follows:

- i. To identify and analyze issues of the test case prioritization technique for event sequences test cases.
- ii. To propose an approach based on unique weight for prioritizing the event sequence test cases.
- iii. To automate the proposed approach by providing supporting tool.
- iv. To empirically evaluate and measure the effectiveness and efficiency of the proposed approach. The effectiveness is measured in terms of its capability to detect faults early, while the efficiency is based on the prioritization ranking.

### 1.4 Research Scope

Numerous TCP techniques have been proposed by many researchers. Most of the proposed techniques use one or more factors to determine the priority value for test cases. Our research proposed a TCP technique for both regression and non-regression testing since no historical data is required for calculating the priority value. However, this research focuses on testing a module that consist of several functions sharing a private data structure (i.e. modules that have memory). For such components, their test cases is in the form of sequence of events, and not a single event. Therefore, the proposed TCP technique is specifically developed to determine the priority value of event sequences test cases.

### **1.5 Research Contributions**

This research aimed to enhance the TCP technique based on the gaps left by previous work in this field. Based on the limitations and gaps, this research has made the following contributions:

- i. It has defined the issues that have been left out by the existing works in prioritizing the event sequence test cases that occur during the prioritization process (C. Y. Huang et al., 2010; Roongruangsuwan & Daengdej, 2010).
- ii. It implemented a tool support for automating the prioritization process suggested by MFWA technique. The MFWA tool can be applied in any related experimental work to test other test cases capability in detecting faults.
- iii. The empirical result was gained based on the comparisons and evaluations made between the random technique and the MFWA technique. The measurement used the same test suite and codes, but different approaches. The effectiveness of the proposed approach was measured in terms of its capability to detect faults earlier than other techniques. Meanwhile the efficiency was measured in terms of how quickly each technique is capable of detecting faults by referring to the position of the test case that capable to killed mutants.

### 1.6 Thesis Organization

This thesis comprises of seven chapters. The first chapter consists of the introduction of this research. Hence, the research problem, the objective and scope, as well as the contributions of this research are also described in the first chapter.

The second chapter presents the detailed study of the existing TCP technique. The research background, which consisted of the issues that have been left out by the existing works, are discussed in detail in this chapter. Apart from that, two key areas are focused on, whereby this research looked into how previous studies handled the same issue of priority value and how they applied the proposed approach in the event sequence test cases. The knowledge gaps left by previous works are also highlighted in this chapter.

The third chapter presents the methodology involved in this research. The research methods, materials or resources, and the deliverables obtained throughout the phases are explained in this chapter. Generally, this chapter highlights the three phases that have been previously defined, namely, the definition of the analysis and problems, the design and development of the tool to support the proposed approach, and finally, the evaluation phase involved in producing the empirical result.

5

The fourth chapter describes the conceptual design of the MFWA technique using six factors. Details of the reasons for the selection of the six factors and how each of the factors produced the weight to be used in the last stage of the prioritization process are explained in this chapter.

The fifth chapter describes the implementation of the MFWA technique, which involved six factors. This chapter discusses in detail how each factor was processed during the tool execution phase.

The sixth chapter presents the experimental procedure and the results of the experiments using the MFWA technique. It provides the statistical analysis using the Paired T-Test statistical model.

The final chapter is Chapter Seven, which consists of the conclusion and future works for this research. Some suggestions for future work that can be investigated by future researchers are explained in this chapter.

### **BIODATA OF STUDENT**

Johanna Ahmad was born on July 20, 1982 in Johor, Malaysia. She started her primary education in Sekolah Kebangsaan Kampung Melayu, Kluang, Johor for six years. Then, she attended Sekolah Tinggi Segamat and Sekolah Tinggi Kluang to complete her secondary education. In 2000, she was accepted to pursue her diploma in Computer Science at Universiti Teknologi Mara. She was promoted to pursue her degree in 2003, and then received a Bachelor's degree in Information System Engineering in October 2006. She worked in the software sector from 2007 to 2009 as a Software Engineer. One year later, she joined the government sector as an Information Technology Officer at the Prime Minister's Department, Malaysia. Her job scope was focused on database management. She was also pursuing a postgraduate degree at Universiti Putra Malaysia and graduated with an MSc. in Computer Science (Software Engineering) in 2012. In September 2015, she enrolled as a full-time student at Universiti Putra Malaysia, where she pursued her PhD in Software Engineering. She is currently an Information Technology Officer at the Prime Minister's Department for Malaysia, Putrajaya.

## STATUS CONFIRMATION FOR THESIS / PROJECT REPORT AND COPYRIGHT

ACADEMIC SESSION :

### TITLE OF THESIS / PROJECT REPORT :

MULTIFACTOR APPROACH TO PRIORITIZE EVENT SEQUENCE TEST CASES

#### NAME OF STUDENT: JOHANNA BINTI AHMAD

I acknowledge that the copyright and other intellectual property in the thesis/project report belonged to Universiti Putra Malaysia and I agree to allow this thesis/project report to be placed at the library under the following terms:

- 1. This thesis/project report is the property of Universiti Putra Malaysia.
- 2. The library of Universiti Putra Malaysia has the right to make copies for educational purposes only.
- 3. The library of Universiti Putra Malaysia is allowed to make copies of this thesis for academic exchange.

I declare that this thesis is classified as :

\*Please tick (V)
