October 2019

Chair : Gan Wan Ying, PhD Faculty : Medicine and Health Sciences

Dental caries in primary teeth is a serious public health issue among children and it is the most common chronic disease worldwide. Dental caries in primary teeth brings detrimental impacts on child growth and development, as well as their quality of life. As there are limited studies determining risk factors of dental caries in primary teeth among pre-schoolers in Malaysia, this cross-sectional study aimed to determine the associations between parental factors and child factors with dental caries in primary teeth among pre-schoolers in *Tabika Perpaduan* in Seremban, Negeri Sembilan, Malaysia.

A total of 396 pre-schoolers (boys: 49.5%; girls: 50.5%) with a mean age of 5.50±0.62 years, from 26 randomly selected *Tabika Perpaduan* in Seremban participated in this study. Dental examination was conducted by a dentist from Hospital Tuanku Ja'afar Seremban to record the amount of decayed and filled primary teeth (dft), salivary pH, and presence of visible plaque. Height and weight of the pre-schoolers were measured by the researchers. Information regarding sociodemographic characteristics, feeding practices, oral health knowledge, attitude and behaviours, second-hand smoke exposure, types of sugary food or drinks, as well as frequency and amount of sugar was gathered through a self-administered questionnaire answered by the mothers. A 3-day food record and food frequency questionnaire were also completed by the mothers.

Results showed that nearly two-third of the pre-schoolers (64.4%) had dental caries in primary teeth, in which higher proportion of boys (69.4%) experienced dental caries than girls (59.5%;  $\chi^2$ =4.221, *p*=0.040). On average, each pre-schooler in this study had nearly four decayed or filled primary teeth (mean±SD dft score=3.66±4.61). Half of the pre-schoolers (52.0%) had visible plaque on

their primary teeth. In term of nutritional status, 14.8% of the pre-schoolers were overweight and obese, while 11.8%, 6.9%, and 7.4% were underweight, stunted, and wasted/thin, respectively. The mean energy intake of the pre-schoolers was 1382±293 kcal, with 37.1% of them did not achieve recommended daily energy intake. One in ten of the pre-schoolers (10.6%) was exposed to sugar for more than six times daily. Bread and bun (63.4%) were the most frequently consumed food, followed by biscuits (62.8%), fruits cordial (50.8%), and flavoured snack (50.4%). Half of the pre-schoolers (51.4%) were living in a household which at least one cigarette was smoked inside the house.

Multiple logistic regression results showed that pre-schoolers with visible plaque on their teeth (AOR=5.64, 95% CI=2.02-10.56), who were Malay (AOR=4.18, 95% CI=1.16-15.06) or Chinese (AOR=7.59, 95% CI=1.57-36.09), who were from household with at least one cigarette smoked inside the house (AOR=2.43, 95% CI=1.15-5.11), total sugar exposure for more than six times daily (AOR=6.40, 95% CI=1.86-22.02), who did not achieve daily recommended energy intake (AOR=2.82, 95% CI=1.50-5.32), daily intake of fruits flavoured drinks or cordial (AOR=4.11, 95% CI=1.50-11.27), and non-daily intake of honey (AOR=3.99, 95% CI=1.13-14.10) had higher risk of developing dental caries in primary teeth. However, the finding on the association of honey and dental caries should be interpreted cautiously because only 4.9% of the pre-schoolers consumed honey daily in this study, which may lead to lower chance of dental caries among this group of pre-schoolers. More *in vitro* and *in vivo* studies are needed to determine the exact mechanism and the potential application of honey in the prevention of dental caries.

In conclusion, a high prevalence of dental caries in primary teeth was found in this study. Promoting good oral hygiene, reducing exposure to second-hand smoke, and practicing healthy eating behaviours may help to reduce risk of dental caries among pre-schoolers. Nutritionists should provide specific dietary guidance for parents of young children, particularly regarding sugary food consumption in order to prevent dental caries in pre-schoolers. Abstrak tesis yang dikemukakan kepada Senat Universiti Putra Malaysia sebagai memenuhi keperluan untuk Ijazah Master Sains

#### FAKTOR BERKAITAN DENGAN RISIKO KARIES GIGI SUSU DALAM KALANGAN KANAK-KANAK PRASEKOLAH DI SEREMBAN, MALAYSIA

Oleh

#### LEE ZHI LING

Oktober 2019

#### Pengerusi : Gan Wan Ying, PhD Fakulti : Perubatan dan Sains Kesihatan

Karies gigi susu adalah isu kesihatan awam yang serius dalam kalangan kanakkanak dan ia adalah penyakit kronik yang paling biasa di seluruh dunia. Karies gigi susu membawa impak yang serius kepada perkembangan dan pertumbuhan, dan juga kualiti hidup kanak-kanak. Kajian mengenai faktor berkaitan dengan karies gigi susu dalam kalangan kanak-kanak prasekolah di Malaysia adalah terhad. Oleh itu, tujuan kajian keratan rentas ini adalah untuk menentukan hubungan antara faktor ibu bapa dan faktor kanak-kanak dengan karies gigi susu dalam kalangan kanak-kanak prasekolah di Seremban, Negeri Sembilan, Malaysia.

Seramai 396 kanak-kanak prasekolah (lelaki: 49.5%; perempuan: 50.5%) dengan purata umur 5.50±0.62 tahun, dari 26 buah Tabika Perpaduan di Seremban yang dipilih secara rawak telah mengambil bahagian dalam kajian ini. Pemeriksaan pergigian dijalankan oleh seorang pegawai pergigian kanak-kanak dari Hospital Tuanku Ja'afar Seremban untuk merekodkan jumlah gigi susu yang berlubang dan ditampal (dft), pH air liur, dan kehadiran plak pada gigi. Ketinggian dan berat badan kanak-kanak diukur oleh penyelidik. Maklumat tentang ciri-ciri sosiodemografik, amalan penyusuan ibu, pengetahuan, sikap and tingkah laku tentang kesihatan pergigian kanak-kanak, pendedahan kepada asap rokok dalam rumah, jenis makanan dan minuman, dan kekerapan makan makanan dan minum minuman yang manis telah dikumpulkan melalui soal selidik yang diisi oleh ibu kanak-kanak. Rekod makanan tiga hari dan soal selidik kekerapan makanan juga dilengkapkan oleh ibu.

Hasil kajian menunjukkan bahawa hampir dua pertiga kanak-kanak (64.4%) mempunyai masalah karies gigi susu, di mana lebih ramai lelaki (69.4%) mempunyai karies gigi berbanding dengan perempuan (59.5%;  $\chi^2$ =4.221, p=0.040). Secara puratanya, setiap kanak-kanak dalam kajian ini mempunyai

hampir empat gigi susu yang berlubang atau ditampal (min±SD skor dft=3.66±4.61). Separuh kanak-kanak (52.0%) mempunyai plak pada gigi susu. Dari segi status pemakanan, 14.8% kanak-kanak mengalamai masalah berlebihan berat badan dan obesiti, manakala 11.8%, 6.9%, dan 7.4% kanak-kanak adalah kurang berat badan, terbantut, dan kurus. Purata pengambilan tenaga kanak-kanak adalah 1382±293 kcal, dengan 37.1% kanak-kanak tidak mencapai pengambilan tenaga harian yang disyorkan. Satu daripada sepuluh orang kanak-kanak (10.6%) terdedah kepada gula lebih daripada enam kali sehari. Roti (63.4%) adalah makanan yang paling kerap dimakan, diikuti oleh biskut (62.8%), kordial buah-buahan (50.8%), dan snek berperisa (50.4%). Separuh kanak-kanak (51.4%) tinggal di rumah yang sekurang-kurangnya satu batang rokok dihisap di dalam rumah.

Hasil regrasi pelbagai logistik menunjukkan bahawa kanak-kanak yang terdapat plak pada gigi susu (AOR=5.64, 95% CI=2.02-10.56), berbangsa Melayu (AOR=4.18, 95% CI=1.16-15.06) atau Cina (AOR=7.59, 95% CI=1.57-36.09), berasal dari rumah dengan sekurang-kurangnya satu batang rokok dihisap di dalam rumah (AOR=2.43, 95% CI=1.15-5.11), terdedah kepada gula lebih daripada enam kali sehari (AOR=6.40, 95% CI=1.86-22.02), tidak mencapai pengambilan tenaga harian yang disyorkan (AOR=2.82, 95% CI=1.50-5.32), mengambil minuman atau kordial yang berperisa buah-buahan setiap hari (AOR=4.11, 95% CI=1.50-11.27), dan tidak mengambil madu setiap hari (AOR=3.99, 95% CI=1.13-14.10) terdapat risiko yang tinggi untuk karies gigi susu. Walau bagaimanapun, hasil kajian ini mengenai hubungkait antara pengambilan madu dan karies gigi perlu diinterpretasikan dengan berhati-hati kerana hanya 4.9% kanak-kanak prasekolah yang makan madu setiap hari dalam kajian ini, yang berkemungkinan membawa kepada peluang yang lebih rendah untuk mendapat karies gigi dalam kalangan kumpulan kanak-kanak prasekolah ini. Lebih banyak kajian in vitro dan in vivo diperlukan untuk menentukan mekanisme dan penggunaan madu dalam pencegahan karies gigi.

Kesimpulannya, prevalen karies gigi susu yang tinggi didapati dalam kajian ini. Penggalakkan kebersihan pergigian yang baik, pengurangan pendedahan kepada asap rokok, dan pengamalan tingkah laku pemakanan yang sihat dapat membantu mengurangkan risiko karies gigi dalam kalangan kanak-kanak. Pakar pemakanan harus menyediakan panduan diet yang spesifik untuk ibu bapa, khususnya mengenai pengambilan makanan manis untuk mencegah karies gigi dalam kalangan kanak-kanak prasekolah.

#### ACKNOWLEDGEMENTS

First of all, I would like to express my sincere thanks and appreciation to my supervisor, Associate Professor Dr. Gan Wan Ying for her guidance, encouragement, support and patience throughout my master journey. She was always there to provide guidance whenever I faced problems in my research or writing. Also, I would like to extend my gratitude to my co-supervisors, Dr. Lim Poh Ying and Dr. Ruhaya Hasan for their valuable ideas, encouragement and continuous support, making this research better. Not to forget Dr. Lim Sing Ying, paediatric dental specialist from Hospital Tuanku Ja'afar Seremban who volunteer to conduct oral examination for the research. Her dedication to the research is very much appreciated.

Moreover, I would like to thank Universiti Putra Malaysia for funding this research through Putra Graduate Initiative (IPS) Grant (Grant No.: GP-IPS/2018/9652600). I feel deeply grateful to receive scholarship from Graduate Research Fellowship (GRF) from Universiti Puta Malaysia for the financial support throughout my master journey. In addition, I would like to thank Oral Health Division, Ministry of Health and Department of National Unity and Integration (JPNIN) for allowing me to conduct the research among pre-schoolers in *Tabika Perpaduan* in Seremban, Negeri Sembilan. Not forgetting to thank the teachers in the participating pre-schoolers and parents who have participated in the research. Special thanks to enumerators who have helped in the data collection.

Lastly, I would like to give my special thanks to my family and friends for their endless support, understanding, and love. They are always my best listeners whenever I need an ear. I could not have completed this research without anyone mentioned above. Sincere gratitude to all of them.

This thesis was submitted to the Senate of Universiti Putra Malaysia and has been accepted as fulfilment of the requirement for the degree of Master of Science. The members of the Supervisory Committee were as follows:

#### **GLOSSARY OF TERMS**

dmft index Total number of decayed, missing and filled primary teeth (WHO, 2013).

DMFT index Total number of decayed, missing and filled permanent teeth (WHO, 2013).

Dental caries in primary Presence of one or more decayed (noncavitated or cavitated lesions), missing (due to teeth caries), or filled tooth surfaces in any primary tooth (AAPD, 2008).

Early childhood caries Presence of one or more decayed (noncavitated or cavitated lesions), missing (due to caries), or filled tooth surfaces in any primary tooth in a child younger than 71 months old (AAPD, 2008).

Severe early childhood Happens when children younger than 3 years old have any sign of smooth surface caries. For children aged 3 through 5 years, one or more cavitated, missing (due to caries), or filled smooth surfaces in primary maxillary anterior teeth or a dmft score of  $\geq 4$  (age 3),  $\geq 5$  (age 4), or ≥6 (age 5) (AAPD, 2008).

Sugar exposure

caries

Frequency of solid and liquid sugar consumption in a day (Palmer & Boyd, 2016).

#### CHAPTER 1

#### INTRODUCTION

#### 1.1 Background

Primary teeth, also known as baby teeth or deciduous teeth, usually erupt between 6 months after birth to around 4 years (Friedman, 2017). The teeth erupt in the sequence of primary central incisors, lateral incisors, first molars, canines to second molars (Friedman, 2017). By 2 or 3 years old, all 20 primary teeth come in. Before the eruption of permanent teeth, primary teeth play an important role in reserving space for permanent teeth and the development of clear speech (Friedman, 2017). However, primary teeth usually come with immature enamel (Gussy, Waters, Walsh, & Kilpatrick, 2006). Hence, appropriate dental care should be applied as primary teeth with immature or underdeveloped enamel may have higher risk of developing caries (Caufield, Li, & Bromage, 2012).

The period after emergence of first tooth until its complete maturation is the period when it is the most vulnerable to caries development (Vadiakas, 2008). Enamel of primary teeth is specifically susceptible to the presence of cariogenic bacteria (Geddes, 1975). These bacteria release acidic substances, hydrogen ions during the metabolic activities of fermenting carbohydrate (such as glucose, sucrose, fructose or cooked starch) and form biofilm on the teeth (Geddes, 1975). The hydrogen ions dissolve the carbonated hydroxyapatite crystal lattice of enamel, cementum, and dentin (Featherstone, Nelson, & McLean, 1981; LeGeros, 1991). Cavitated enamel which results from demineralization further supports growth of bacteria, as it is difficult to remove biofilm from rough cavitated enamel (Kawashita, Kitamura, & Saito, 2011). When the caries balance on the enamel is disrupted in a way that demineralization is more than remineralization, the development of caries occurs (Featherstone, 2000).

Dental caries (also known as tooth decay or dental cavities) in primary teeth is a serious public health issue among children and it is the most common noncommunicable disease worldwide (WHO, 2018a). Among 5- to 17-year-old children in the United States of America (USA), dental caries is five times more common than asthma and seven times than hay fever (U.S. Department of Health and Human Services, 2000). In 2010, almost 9% of the children worldwide affected by untreated caries in primary teeth (Kassebaum et al., 2015). The prevalence of dental caries in primary teeth in some developed countries such as the USA (23%) and the United Kingdom (UK; 28%) are relatively low compare to the prevalence in developing countries such as Philippines (88%) and Laos (89%) (Duangthip, Gao, Lo, & Chu, 2017; Dye, Thornton-Evans, Li, & Iafolla, 2015; Holmes et al., 2015). Dental caries in primary teeth is also prevalent in some Middle Eastern countries, such as Palestine (76%) and the United Arab Emirates (83%) (Azizi, 2014; El-Nadeef, Hassab, & Al-Hosani, 2010). In most of the Southeast Asia countries, such as Philippines (88%), Laos (89%) and Cambodia (90 - 93%), the prevalence of dental caries in primary teeth was more than 85%, except for Brunei (59%) and Singapore (49%) (Duangthip et al., 2017). In addition, children from other countries in Asia, such as Hong Kong (51%), China (66%), and India (54%) have relatively lower prevalence of caries in comparison with countries in Southeast Asia (Department of Health, 2011; Hu, Hong, & Li, 2011; Mahejabeen, Sudha, Kulkarni, & Anegundi, 2006). The disparities between prevalence of caries in developed and developing countries could be a result of distinct risk profiles across Southeast Asia countries, such as low number of dentistry personnel (WHO, 2011), insufficcient equipment, lower fluoride coverage, poor socio-economic status, and possibly lack of political attention, particularly in low-income and middle-income countries (Benzian et al., 2011). Furthermore, the density of dentist per 10 000 population in Southeast Asia Region (0.7) was the lowest among the WHO regions, compared to Region of the Americas (12.0) and European Region (4.9) (WHO, 2011). This incidates that countries in Southeast Asia do not have enough oral health workforce who are able to provide oral health care for all populations, which then leads to high caries prevalence among the countries. Another interesting phenomenon is that, although Brunei (59%) and Singapore (49%) are developed countries (Duangthip et al., 2017), the prevalence in both countries are still considered high compared to other developed countries such as USA (23%) and the United Kingdom (UK; 28%) (Dye et al., 2015; Holmes et al., 2015). This could be due to the cultural differences as countries in Southeast Asia tend to have higher carbohydrates intake, which might be cariogenic, compared to dietary pattern in Western countries.

Moving back to the context of Malaysia, the national oral health survey reported a notable decrease in the prevalence of dental caries among Malaysian children, especially those in pre-school age. The survey reported that caries prevalence decreased from 87.1% in 1995 to 76.2% in 2005 among 5-year-old Malaysian children (Oral Health Division Ministry of Health Malaysia, 2007), whereas, among the 6-year-old Malaysian children, caries prevalence decreased from 80.9% in 1997 (Oral Health Division & Ministry of Health Malaysia, 1998) to 74.5% in 2007 (Oral Health Division Ministry of Health Malaysia, 2009). Although the prevalence of dental caries in children has decreased, it is still considered a serious public health issue. The disease burden remains significant among children especially those in the socioeconomically disadvantaged groups due to their changing lifestyle and dietary pattern (Khairiyah, Wan Mohd Nasir, Yaw, & Norliza, 2013).

Although dental caries in primary teeth is transmissible, it is preventable by routine dental check-up, good oral hygiene, and healthy eating behaviours. In order to create evidence-based effective prevention strategies, it is important for researchers to examine the factors related to the disease at different levels such as community, family, and individual levels. Identifying risk factors of dental caries among pre-schoolers would be especially valuable in order to develop prevention programs and update clinical practice guidelines. Most importantly, prevention and early treatment of dental caries would improve oral health as well as overall health of children.

#### 1.2 Problem Statement

Caries is ranked as the fourth most expensive chronic disease to treat according to WHO (Petersen, 2008), where it is one of the most prevalent chronic diseases among children (Nakayama & Mori, 2015a). It was estimated that yearly direct treatment cost on dental disease worldwide was 298 billion US dollar in 2010 (Listl, Galloway, Mossey, & Marcenes, 2015). Furthermore, the estimated indirect cost, such as loss of productivity, due to dental disease amounted to 144 billion US dollar yearly (Listl et al., 2015). This showed that the total amount of direct and indirect costs was 442 billion US dollar for 2010 alone. However, there is no record of cost spent on dental disease in Malaysia.

Beyond the economic impact, untreated caries on primary teeth also bring serious impacts to the general health, as well as quality of life of the children (Martins-Júnior et al., 2013). Children with caries experienced difficulty in eating and sleeping due to the unbearable pain and soreness (Gilchrist, Marshman, Deery, & Rodd, 2015). In turn, the children may change their diet and avoid some food that is difficult to chew. The chewing problem and pain affect their nutrients intake lead to poor growth and development (Van Cauter & Plat, 1996). Furthermore, as the disease progresses without any intervention, teeth of the children loss inevitably and this may influence their speech development (Kumarihamy, Subasinghe, Jayasekara, Kularatna, & Palipana, 2011). These children would develop low self-esteem. If it is not treated well, caries might end up fatal (Duangthip et al., 2017). A previous cohort study reported that children with caries in their primary teeth were three times more likely to develop caries in their permanent teeth (Li & Wang, 2002). Undoubtedly, dental caries is a major oral health problem in childhood that warrants further attention.

Dental caries is a multifactorial disease involving various risk and protective factors. Managing multiple factors occurs during pre-school years are crucial in maintaining the caries balance and preventing dental caries. These factors included parental and child factors, such as dental plaque, frequent contact with fermentable carbohydrates through improper feeding practices, as well as a series of sociodemographic factors such as parental educational level, employment status, and monthly household income (Hong, Levy, Warren, & Broffitt, 2014; Mattheus, Gandhi, Lim, & Shannon, 2017; Tanner et al., 2011). Only two published studies were conducted to examine risk factors of dental caries in primary teeth among pre-schoolers in Malaysia (Ruhaya et al., 2012; Zahara, Fashihah, & Nurul, 2010). These two studies mainly focused on body mass index (BMI), frequency of sugary food and drinks consumption and dental caries. Other local studies have mainly focused on measuring dental caries and its associated factors such as BMI, sugar consumption, oral health practice and oral hygiene among primary school children (Kaur, Maykanathan, & Ng, 2015; Masood, Yusof, Hassan, & Jaafar, 2012). The current study aimed to fill in the knowledge gap on the associations between multiple factors such as feeding practices, birth weight, sugar exposure, oral health knowledge, attitude and behaviours with dental caries in primary teeth among pre-schoolers.

Improper feeding practices included late initiation of breastfeeding, early/late introduction of complementary food, prolonged breastfeeding, breast- or bottlefeeding before bedtime, sleep with bottle in mouth, affect children's health and development. Previous studies have shown that improper feeding practices such as prolonged breastfeeding (breastfeed for more than 24 months), breast- or bottle-feeding before bedtime or sleep with bottle in mouth were found to be associated with dental caries in primary teeth (Nakayama & Mori, 2015a; Prakash, Subramaniam, Durgesh, & Konde, 2012; Slabšinskiene et al., 2010; Wong et al., 2017). However, the relationship of shorter or longer duration of breastfeeding with dental caries in primary teeth is still inconclusive (Hong et al., 2014; Tanaka & Miyake, 2012; Zhou, Lin, Lo, & Wong, 2011). Nevertheless, most of the studies did not address the frequency of breastfeeding in a day. In contrast, some studies found insignificant association between feeding practices and dental caries in children (Nunes et al., 2012; Tham et al., 2015). Prolonged feeding and bottle feeding before sleep were prevalent among Malaysian mothers (IPH, 2016b). However, the association of these improper feeding practices (prolong breastfeeding, breast- or bottle-feeding before bedtime or sleep with bottle in mouth) and dental caries in primary teeth of pre-schoolers has not been examined by local researchers.

Parents play a crucial role in constructing their children's good oral health behaviours. Mothers' knowledge and attitudes about oral health (Li et al., 2011; Wulaerhan, Abudureyimu, Bao, & Zhao, 2014) as well as children's practices related to tooth brushing (Kaur et al., 2015; Kowash, Alkhabuli, Dafaalla, Shah, & Khamis, 2017; Li et al., 2011; Slabšinskienė et al., 2010) and dental visit (Huong et al., 2017; Kumarihamy et al., 2011) are usually parts of the factors that researchers would focus on. However, inconsistent findings were reported. Furthermore, there was only one published study in Malaysia focused on maternal oral health related knowledge, attitude and behaviours (Mani, John, Ping, & Noorliza Mastura, 2012). Therefore, study examining maternal oral health knowledge, attitude and behaviours and its association with dental caries of pre-schoolers is much needed.

Young children are not likely to smoke actively, but three out of five young children were exposed to the effects of second-hand smoke (Mattheus et al., 2017; WHO, 2008). It is suggested that exposure to second-hand smoke in house increase risk of caries among children by increasing the attachment of cariogenic bacteria on teeth surfaces and decreasing immune function (Hanioka, Ojima, Tanaka, & Yamamoto, 2011; Mattheus et al., 2017; Nakayama & Mori, 2015b; Watanabe et al., 2014) but several studies found no association (Paglia et al., 2016; Wulaerhan et al., 2014). In addition, evidence on the association of maternal smoking during first trimester or throughout the pregnancy period with caries among children is insufficient (Tanaka, Miyake, Nagata, Furukawa, & Arakawa, 2015). Most of the previous studies that examined factors of caries in primary teeth did not take into account of second-hand smoke exposure, which is an important factor to be investigated further. The role of second-hand smoke exposure in dental caries was poorly examined among Malaysian pre-schoolers.

Early childhood is an important period in forming dietary habit, which is a denotation of later health of a child. Dietary practices such as frequent consumption of sugar-sweetened beverages (SSBs), sucrose intake (sugary juices, baby formula, snacks, or candies) between meals or free sugar (added sugars in food or drinks) consumption before bedtime were found to be associated with the increasing risk of dental caries (Do, Ha, & Spencer, 2015; Goodwin et al., 2017; Nunes et al., 2012). On the contrary, two local studies did not find any association between frequency of sugary food and drink consumption with caries (Kaur et al., 2015; Zahara et al., 2010). Since there are a variety of dietary practices in different ethnic groups in Malaysia, there is a need to examine the associations of sugary food, drinks or snack intake and dental caries among pre-schoolers.

Obesity and caries are health problems that exist concurrently in many populations, mostly due to common risk factors, including consumption of food with high calorie, increased stress, and low socioeconomic status (Chi, Luu, & Chu, 2017). The findings on the associaiton between BMI and dental caries are still inconslusive as some of the studies found positive association (Alm et al., 2011; Docimo et al., 2014; Pikramenou, Dimitraki, Zoumpoulakis, Verykouki, & Kotsanos, 2016) while other studies found negative association (Alkarimi, Watt, Pikhart, Sheiham, & Tsakos, 2014; Dimaisip-Nabuab et al., 2018; Norberg, Hallström Stalin, Matsson, Thorngren-Jerneck, & Klingberg, 2012). However, some studies have found insignificant findings (Kaur et al., 2015; Ruhaya et al., 2012; Yen & Hu, 2013). As a developing country facing double burden of malnutrition, a study that determining the relationship between BMI and dental caries among pre-schoolers is very much needed.

Understanding the salivary environment is critical in achieving long-term oral health of children. Oral hygiene such as saliva pH and visible plaque may affect dental caries (Animireddy et al., 2014; Tanner et al., 2011; Zhou et al., 2011). Children with lower salivary pH (Animireddy et al., 2014; El-Kwatehy & Youssef, 2016; Makawi, El-masry, & El-din, 2017) and more visible plaque (Parisotto et al., 2015; Tanner et al., 2011; Zhou et al., 2011) were found to have higher prevalence of dental caries. Nevertheless, null findings regarding pH were shown in other studies (Normastura, Norhayani, Azizah, & Mohd Khairi, 2013; Nunes et al., 2012; Paglia et al., 2016). As oral hygiene could be possible early indicator of dental caries and there was lack of study in oral hygiene among Malaysian pre-schoolers, these suggest the needs to include these variables in this study.

In general, it is crucial to determine risk factors of dental caries in primary teeth among Malaysian children as limited local studies have been conducted. The Oral Health Division, Malaysia has been advocating local researchers to identify predictors of dental caries in children (Oral Health Division, 2008). Additionally, diet, nutrition and dental caries are linked but very few studies investigated this link. Hence, this study aimed to determine the associations between parental factors and child factors with dental caries in primary teeth among pre-schoolers in Seremban, Negeri Sembilan, Malaysia. There are a few research questions to be addressed in this study:

- 1) What is the prevalence of dental caries in primary teeth among preschoolers in *Tabika Perpaduan* at Seremban?
- 2) Are parental factors and child factors associated with dental caries in primary teeth among pre-schoolers in *Tabika Perpaduan* at Seremban?

#### 1.3 Significance of the Study

Dental caries in primary teeth is a multifactorial disease. Different parental and child factors influence the development of this disease. The findings of this study could fill in the gap of knowledge, as there was limited study regarding dental caries in primary teeth in Malaysia. Moreover, multiple factors but not a single factor has been included in the current study to determine their associations with dental caries in primary teeth among pre-schoolers. Extensive understanding on the factors associated with dental caries in primary teeth of pre-schoolers is important in order to develop appropriate prevention strategies on dental caries as well as intervention programs on oral health. Furthermore, this study provides baseline data for future research related to dental caries in children.

Findings of this study could help policy makers to develop targeted policy and guidelines for healthcare personnel and parents to improve oral health of children, and eventually decrease the prevalence and severity of dental caries among children. Healthcare personnel such as nutritionists, dietitians, dentists or any other authorities could also make use of the findings of this study to develop effective intervention programs for children and parents by educating them about proper oral health behaviours and healthy eating behaviours. As this study focused on parental factors, particularly feeding practices, oral health knowledge and attitude, dental care professionals and parents can work together to create an oral health care plan to improve and prevent the development of dental caries in primary teeth among children.

#### 1.4 Research Objectives

#### 1.4.1 General objective

To determine the factors associated with dental caries in primary teeth among pre-schoolers in *Tabika Perpaduan* in Seremban.

#### 1.4.2 Specific objectives

1) To examine parental factors (age, marital status, parental education level, monthly household income level, feeding practices, maternal oral health knowledge and attitudes) and child factors (sex, age, birth order,

birth weight, oral health behaviours, second-hand smoke exposure, dietary intake, growth status and oral hygiene) of pre-schoolers.

- 2) To determine the prevalence of dental caries in primary teeth among pre-schoolers.
- 3) To determine the associations of parental factors and child factors with dental caries in primary teeth among pre-schoolers.
- 4) To determine the contributions of parental and child factors toward dental caries in primary teeth among pre-schoolers.

#### 1.5 Research Hypotheses

- 1) There are significant associations of parental factors and child factors with dental caries in primary teeth among pre-schoolers in *Tabika Perpaduan* in Seremban.
- 2) There are significant contributions of parental factors and child factors toward dental caries in primary teeth among pre-schoolers in *Tabika Perpaduan* in Seremban.

#### 1.6 Conceptual Framework

As shown in Figure 1.1, dental caries in primary teeth is the dependent variable while parental factors and child factors are the independent variables of this study.

Several studies have found that being a female, older age, being first-born or lower parental education level were associated with higher prevalence of dental caries among children (Hong et al., 2014; Kaur et al., 2015; Kumarihamy et al., 2011; Yen & Hu, 2013). There are more children experienced caries when their mothers practiced improper feeding practices, such as prolonged breastfeeding (more than 24 months), nocturnal breast- or bottle-feeding (Nakayama & Mori, 2015; Slabšinskienė et al., 2010; Wong et al., 2017). Mothers with poor oral health knowledge and attitude were more likely to have children with dental caries (Bennadi et al., 2014; Li et al., 2011).

Childen who did not did not follow recommendations of oral health practices, such as shorter time of teeth brushing, did not start tooth brushing after eruption of first teeth, older age of commencing tooth brushing, had higher risk of dental caries (Kaur et al., 2015; Kowash et al., 2017; Li et al., 2011; Slabšinskienė et al., 2010). Moreover, second-hand smoke exposure was found to increase the risk of dental caries among children (Mattheus et al., 2017; Watanabe et al., 2014). Furthermore, dietary intake such as frequent consumption of sugar-sweetened beverages and sucrose intake between meals found to increase the risk of dental caries (Do et al., 2015; Hong et al., 2014; Nunes et al., 2012). Palacios et al. (2010) found that higher intake of total carbohydrates, total sugar, sucrose, fructose and inositol were associated with higher odds of caries. Furthermore, Parisotto et al. (2010) also showed that pre-schoolers who exposed to sugar for more than six times daily had higher risk of caries in primary

teeth. On the other hand, Chopra et al. (2015) stated that children who were underweight, overweight and obese had higher risk of developing caries in comparison with normal weight children. Low pH of saliva and high plaque index were found to increased risk of dental caries among children (Animireddy et al., 2014; Tanner et al., 2011; Zhou et al., 2011).

#### **BIODATA OF STUDENT**

Lee Zhi Ling was born in Penang on 19<sup>th</sup> December 1993. Growing up in a healthconscious family, she always believes that best nutrition brings the best body and mind. Hence, she decided to pursue her bachelor's degree in Nutrition and Community Health at Universiti Putra Malaysia (UPM) and completed it in 2017 with First Class Honour. She won an award, named *Pingat Emas Alumni*, as she graduated. She continued to pursue her master's degree in Community Nutrition, under the supervision of Assoc. Prof. Dr. Gan Wan Ying. Her field of research focused on childhood nutrition and dental caries. She presented her findings in national and international conferences such as Asian Congress of Nutrition 2019, which was held at Bali International Convention Center, from 4 to 7 August 2019. The experiences and knowledge gained through the process prepared her for future career pathway.
