## DEDICATION

### **For my beloved family:**

Richard Madis Araji

Evelyn Hong Teo Yong

Also my siblings

To all my friends,

Thank you for your encouragements supports from start to end of my research and the sacrifices that you're helping me.

Last but not least,

I dedicated this dissertation to Norhisham Ahmad Razi

Who has encouraged me, helped and give so much support during conducting this research and in my study.

Thank you for everything.

## ABSTRACT

Forest conversion for agricultural expansion is among the major driver of biodiversity losses worldwide. Agricultural land use, however, may have different impacts on overall biodiversity especially insects. Understanding landscape heterogeneity between monoculture and polyculture systems can improve conservation of insect biodiversity in agricultural plantations. The present study compared terrestrial insect abundance and order richness between polyculture orchard, monoculture rubber and monoculture oil palm plantations. The study was carried out in Kampung Sungai Lalah, Pedas, Negeri Sembilan from January to February 2018. Terrestrial insects were sampled using pitfall traps at all agricultural landscapes (total sampling point = 45). In overall, the study recorded 2555 individuals belonging to 10 insect orders. Polyculture orchard recorded greater insect abundance and order richness followed by monoculture oil palm and monoculture rubber plantations. Polyculture orchard also showed greater vegetation cover and relative humidity. In addition, Dermaptera and Homoptera were also recorded in polyculture orchard and monoculture oil palm plantations. The findings from this study indicate that polyculture systems can support greater insect abundance and diversity due to complex vegetation structure and higher humidity. Local diversity of plants and insects also represent improved ecosystem services such as decomposition rates. The findings suggest that agricultural management should prioritize polyculture systems to improve insects conservation and ecosystems services.

## ABSTRAK

Pembukaan hutan untuk pertanian adalah penyebab utama kemerosotan biodiversiti di muka bumi ini. Penggunaan pertanian mempunyai impak terhadap biodiversiti terutamanya serangga. Pemahaman mengenai kualiti landskap antara sistem monokultur dan polikultur boleh meningkatkan penjagaan terhadap biodiversiti serangga pada penanaman pertanian. Kajian ini membandingkan kepelbagaian dan kekayaan order serangga darat antara polikultur kebun, monokultur getah dan monokultur ladang kelapa sawit. Penyelidikan dibuat di Kampung Sungai Lalah, Pedas, Negeri Sembilan daripada Januari ke Febuari 2018. Serangga darat diambil sampel menggunakan perangkap lubang pada semua landskap pertanian (jumlah sampel = 45). Keseluruhannya, kajian ini merekodkan 2555 bilangan serangga daripada 10 kekayaan order. Polikultur kebun merekodkan kepelbagaian dan kekayaan order serangga yang paling baik dan diikuti oleh monokultur kelapa sawit dan monokultur getah. Polikultur kebun juga menunjukkan vegetasi dan kelembapan relatif yang paling baik. Sebagai tambahan, Dermaptera dan Homoptera direkodkan di polikultur kebun dan monokultur ladang kelapa sawit. Penyelidikan ini menunjukkan sistem polikultur boleh menyokong kepelbagaian serangga dengan struktur vegetasi yang pelbagai dan kelembapan yang tinggi. Tumbuhan tempatan dan serangga membantu perkhidmatan ekosistem seperti penghuraian. Kajian ini menyarankan pengurusan pertanian seharusnya mengutamakan sistem polikultur untuk meningkatkan konservasi serangga dan perkhidmatan ekosistem.

## ACKNOWLEDGEMENTS

Thanks to God for His merciful for giving me strength to do my research and accomplish this project with successfully. First and foremost, I would like to extend my gratitude to all the parties who support me, especially my supervisor, Dr Norhisham Ahmad Razi for his continues guidance, constructive suggestion and precious advice regarding my project throughout the period of my research. His invaluable help have contributed to the success of my research.

Great appreciation to the people has been involved to my research project paper to success. They are residents of Kampung Sungai Lalah, Negeri Sembilan for assistance in giving information about the study site.

Last but not least, my deepest gratitude goes to my family members and friend especially to Megat, Amalina, Aziati, Fatin and Najihah for their support throughout the research. Thanks to all of you.

## APPROVAL SHEET

I certify that this research project report entitled “Comparing Terrestrial Insect Diversity Using Pitfall Trap Under Different Agricultural Landscapes” by Rexie Meekenddey Madis has been examined and approved as a partial fulfillment of the requirements for the Degree of Bachelor of Forestry Science in the Faculty of Forestry, Univeristi Putra Malaysia.

# CHAPTER 1

## INTRODUCTION

### 1.0 Background of Study

Tropical deforestation continues to rise at an alarming rate worldwide (FAO 2015). However, the net loss of forest area has reduced between 2000 to 2010 due to increase global effort in reforestation and afforestation (Achard et al., 2002). The major drivers of tropical deforestation are mainly due to forest conversion into agricultural land use for agricultural products. Agricultural products such as palm oil ensures food security and is a potential source of renewable energy (Sunderland et al., 2017). In Malaysia alone, at least 1,040,000 ha of forest were converted to oil palm from 1990 to 2005 (Wilcove & Koh, 2010). Due to this, tropical forest conversion into oil palm plantations has become one of the major concerns for biodiversity declines. However, agricultural management and practices can be improved to ensure biodiversity conservation as suggested by (Foster et al., 2011) In the study, they suggested that agricultural landscape must contain forest reserves as these ecosystem can conserve forest community and maintain ecosystem functioning. Besides that, retaining forest remnants can provide refuge for forest-dependent species that would not be able to survive in agricultural landscape (Edwards et al., 2010).

Previous studies has shown that the decline in local biodiversity are mainly due to intensification of agricultural management as seen in monoculture systems

(Bengtsson et al., 2005). Local species diversity may increase with environmental friendly farming practices but this is highly dependent on the surrounding area of the landscape (Weibull et al., 2003). The ecological process within an ecosystem may influence local species assemblages due to interactions between different environmental variables (Tscharrntke et al. 2005). Land use effects are represented by two categories; landscape and habitat heterogeneity (Weibull et al., 2003), which is influenced by the presence of natural habitat (Schmidt, 2005). Thus, difference in local species assemblages is mostly influenced by the local environment factor at the landscape level (Schweiger et al 2005).

Tropical rain forest provides refuge for various insect communities. Forest degradation from logging activities and conversion into agriculture land are among the major factor that contributes to population decline of tropical insect species (Sodhi et al. 2010). Insects perform various ecological functions in ecosystem services that include pollination, predation and decomposition (Zhang et al., 2007). Thus, forest degradation may interrupt ecosystem services due to loss of important forest insect species (Didham et al 1996). However, there are insect species that dominate agricultural habitats due to its open area characteristics (Liow et al., 2001).

Even though, habitat heterogeneity in agricultural land is lower compared to forest area, agricultural land still support few insect communities for nesting and food resources.. Insects can become an important ecological indicator to

measure biodiversity friendly practices in agricultural landscapes as seen in many terrestrial insect community such as beetles (Coleoptera), ants (Hymenoptera), termites (Isoptera) and grasshopper (Orthoptera) species (Bruhl & Eltz, 2010; Bazelet & Samways). Terrestrial insect adaptation to their surrounding depends on the environmental variables such as microclimate, soil characteristics and the type of vegetation (Fattorini and Salvati 1999). Some beetle species also depends on floristic composition as they feed on plant leaves and nectar (Cooter 1991). Terrestrial insects is an important agent for ecosystem services as they can improve soil characteristics through soil mixing that support better nutrient cycling for plant growth as seen in dung beetles (Davis & Philips, 2005) termites (Donovan et al., 2001) and ground-dwelling ants (Bruhl & Eltz, 2010).

### **1.1 Problem Statement**

Land conversion from tropical forest area into agriculture landscape has caused a significant loss of insect biodiversity specifically terrestrial insect community (Groc et al., 2017). In spite of their importance to improved soil stability, to investigate the effects of land used changes on terrestrial insect is still scarce. Terrestrial insect community can become an important ecological indicator to compare agricultural management and practices that has the potential to support biodiversity conservation.

## **1.2 Justification**

Terrestrial insects represent an ideal model organism to assess different agricultural systems that is biodiversity friendly. Greater habitat heterogeneity is clearly illustrated in polyculture systems due to complex vegetation structure compared to monoculture systems (Ghazali et al., 2016). However, different monoculture plantations such as oil palm and rubber plantations may support different terrestrial insect community. The present study will provide more information regarding terrestrial insect community between monoculture and polyculture systems. The results will highlight the importance of terrestrial insect for ecosystems services in agricultural landscapes.

## **1.3 Research Objectives**

The present study set out to determine terrestrial insect species composition and distribution between three different agricultural landscapes. The specific objective is to compare terrestrial insect species richness and abundance between monoculture (oil palm and rubber plantations) and polyculture (fruit orchard) systems. To achieve this, the present study ask the following questions;

(i) Is there any changes in terrestrial insect community between monoculture and polyculture systems and (ii) how changes in vegetation structure influence terrestrial insect species richness and abundance.
