**Faculty : Engineering**

Exposure to a whole-body vibration is an occupational risk factor, which leads to research interests in biodynamic responses of a human body. The knowledge of biodynamic responses of a seated human body on a suspension seat are limited as previous studies were merely focused on the rigid and conventional seats. The main objective of this thesis is to predict the seat transmissibility of a seated human body on the agriculture suspension seat. In addition, factors affecting the seat transmissibility and the apparent mass, such as postures and vibration magnitudes are also investigated. In the first experiment, the vertical seat transmissibility and the Seat Effective Amplitude Transmissibility (SEAT) values were measured. Eleven healthy male subjects aged between 21 to 35 years old, with a mean weight and height of 61.5 kg, and 1.68 m, respectively participated in the study. All the subjects were exposed to random vertical vibration in the range of 1 to 20 Hz, at three vibration magnitudes (0.5, 1.0 and 2.0 m/s<sup>2</sup> r.m.s.) for 60 s. For each exposure, four postures were investigated (“relax”, “slouch”, “tense”, and “backrest”). The results showed that the primary resonance frequency of the seat transmissibility for every posture was pronounced between 1.7 and 2.5 Hz. The transmissibility at the resonance was the highest for the “backrest” condition. The results of SEAT values revealed that “slouch” posture showed the highest value (64.7%). In the second experiment, the apparent mass of a seated human body on a rigid and suspension seat were measured. Two sitting conditions were investigated – i) without the backrest and ii) with the vertical rigid backrest. The experimental measurement revealed a lower peak magnitude and resonance frequency of apparent mass without the backrest for a suspension seat (4.0 to 5.2 Hz), as compared to those measured with a rigid seat (4.5 to 5.4 Hz). For both seats, there was a reduction in the peak of apparent mass when in contact with a backrest. In both experiments, there was a reduction in the primary resonance frequency of the seat transmissibility and the apparent mass with an increase in the vibration magnitude, suggesting a non-linearity in the suspension seat-human system. Using the measured apparent mass of the

seated human body on suspension seat, a two-degree-of-freedom lumped parameter model was developed. The model was able to fit the measured responses of the body in various sitting conditions (with and without the backrest). The modelling found that when a human body was in contact with the backrest, the mass decreased and the stiffness increased, resulting in an increase in the derived damped natural frequency. A combined three-degree-lumped-parameter of suspension seat-human body model was developed to predict the suspension seat transmissibility. The model was capable in predicting the seat transmissibility by minimizing the sum-of-least-squares error between the experimental measurements and the model prediction. It was found that the performance of the suspension seat did not depend on the suspension mechanism alone, but rather on the combination of the seated human body with the suspension seat. This research shows that the vibration transmission of a suspension seat can be predicted. Such predictions will assist the optimization of the suspension seat, and thus reduce the time needed to assess the suspension seat performance.

Abstrak tesis yang dikemukakan kepada Senat Universiti Putra Malaysia

## **MERAMAL KEBOLEHPINDAHAN GETARAN MENEGAK SELURUH BADAN PADA MANUSIA KETIKA DUDUK DIKERUSI PENGGANTUNGAN**

Oleh

**SITI AISYAH BINTI ADAM**

September 2020

**Pengerusi : Nawal Aswan bin Abdul Jalil, PhD, PEng**  
**Fakulti : Kejuruteraan**

Pendedahan kepada getaran seluruh badan merupakan risiko pekerjaan, yang menjadi tumpuan dalam penyelidikan respon biodinamik badan manusia. Pengetahuan mengenai respon biodinamik manusia ketika duduk dikerusi sistem penggantungan adalah terhad, kerana kajian terdahulu banyak memberi fokus kepada kerusi rigid dan konvensional. Objektif utama tesis ini adalah untuk menjangka kebolehpindahan getaran kerusi terhadap manusia ketika duduk dikerusi penggantungan pertanian. Selain itu, faktor-faktor yang mempengaruhi kebolehpindahan getaran kerusi dan jisim nyata, seperti postur dan magnitud getaran turut dikaji. Dalam eksperimen pertama, kebolehpindahan getaran kerusi secara menegak dan nilai Kebolehpindahan Efektif Amplitud Kerusi (SEAT) diukur. Sebelas subjek lelaki yang sihat, berumur sekitar 21 hingga 35 tahun, dengan min berat 61.5 kg dan min tinggi 1.68 m mengambil bahagian dalam kajian. Kesemua subjek didedahkan kepada getaran rawak menegak dalam julat 1 hingga 20 Hz, pada tiga magnitud getaran (0.5, 1.0 and 2.0 m/s<sup>2</sup> punca min kuasa dua) selama 60 saat. Pada setiap pendedahan getaran, empat postur diselidik (“mengendur”, “membongkok”, “menegang” dan “bersandar”). Keputusan menunjukkan resonan frekuensi pertama, kebolehpindahan kerusi untuk setiap postur adalah ketara antara frekuensi 1.7 hingga 2.5 Hz. Kebolehpindahan ketika diresonan adalah tertinggi ketika postur “bersandar”. Keputusan SEAT menunjukkan postur “membongkok” mencatat nilai tertinggi (64.7%). Dalam eksperimen kedua, jisim nyata badan manusia ketika duduk dikerusi rigid dan kerusi penggantungan diukur. Dua kedudukan duduk dikaji – i) tanpa sandar dan ii) dengan sandaran rigid menegak. Keputusan ujikaji menunjukkan puncak magnitud dan resonan frekuensi yang lebih rendah pada jisim nyata untuk kerusi penggantungan (4.0 hingga 5.2 Hz), jika dibandingkan dengan kerusi rigid (4.5 hingga 5.4 Hz). Untuk kedua-dua eksperimen, terdapat pengurangan pada resonan frekuensi yang pertama untuk kebolehpindahan kerusi dan jisim nyata apabila magnitud getaran ditambah, menimbulkan cadangan tidak linear dalam sistem kerusi penggantungan-manusia. Dengan

menggunakan jisim nyata yang telah didapati dari badan manusia ketika duduk dikerusi penggantungan, dua darjah kebebasan model parameter bergabung dibangunkan. Model berkenaan berpadanan dengan respon badan yang telah diukur dalam pelbagai kondisi duduk (dengan dan tanpa tempat bersandar). Model menunjukkan apabila badan manusia bersentuhan dengan tempat bersandar, jisim berkurang, manakala unsur kekakuan meningkat, menyebabkan peningkatan dalam unsur teredam frekuensi semula jadi. Kombinasi model parameter bergabung kerusi penggantungan-badan manusia dibangunkan untuk menjangka kebolehpindahan getaran kerusi penggantungan. Model tersebut berjaya menjangka kebolehpindahan getaran kerusi penggantungan dengan meminimumkan ralat jumlah kuasa dua terkecil antara keputusan eksperimen dan model jangkaan. Keputusan menunjukkan prestasi kerusi penggantungan tidak hanya bergantung kepada mekanisma penggantungan sahaja, malah ianya disebabkan oleh gabungan pengaruh badan manusia ketika duduk di atas kerusi penggantungan. Kajian ini membuktikan getaran penghantaran dari kerusi penggantungan boleh dijangka. Jangkaan tersebut dapat membantu mengoptimumkan kerusi penggantungan dan seterusnya mengurangkan masa yang diperlukan untuk menilai prestasi kerusi penggantungan.

## ACKNOWLEDGEMENTS

Alhamdulillah. I would like to take this opportunity to convey my heartfelt thanks and sincere appreciation to all those who have made this journey possible.

First and foremost, praise to Allah the Almighty for making this possible. I would like to express the deepest appreciation to my supervisor, Assoc. Prof. Ir. Dr. Nawal Aswan Abdul Jalil, who truly broadens my knowledge and interest in the world of science and technology through his passion for research. Dr Nawal continuously provided encouragement and was always willing and enthusiastic to assist in any way he could throughout the research project. His much needed guidance and support were perfectly balanced with the freedom he allowed me to discover my own strengths and capabilities.

Special thanks to my supervisory committee members, Dr Khairil Anas Md Rezali and Assoc. Prof. Dr. Ng Yee Guan, who were willing to share their knowledge and advice to answer my questions regarding the experiment works, journal publications and my thesis. Their continuous supports are much appreciated. I would also like to thank Dr. Shamsul and Ir. Adam from the Science and Technology Research Institute for Defence (STRIDE), Malaysia who allowed me to work in their lab.

My sincere appreciation is extended to Dr. Azizan As'aary, Mr. Tajul Ariffin, Mr. Mohd. Saiful, Mr. Muhammad Wildan and Mr. Mohd Zafri for helping me with the experimental preparation and fabrication. I am also appreciative of all my lab buddies for their support during the experimental works.

Most importantly, I would like to thank my family and friends for their love, prayers, supports and encouragements, without whom I would never have enjoyed so many opportunities. Lastly, I would like to express my sincere thanks who have directly and indirectly contributed to my research work. Thank you all.

This thesis was submitted to the Senate of Universiti Putra Malaysia and has been accepted as fulfilment of the requirement for the degree of Doctor of Philosophy. The members of the Supervisory Committee were as follows:

## LIST OF ABBREVIATIONS

AM	Apparent Mass
CSD	Cross Spectral Density
DOF	Degree-of-Freedom
FE	Finite Element
FFT	Fast Fourier Transform
FRF	Frequency Response Function
GOF	Goodness-of-Fit
IEPE	Integrated Electronics Piezo-Electric
LBP	Lower Back Pain
MSD	Musculoskeletal Disorders
OSHA	Occupational Safety and Health Administration
PSD	Power Spectral Density
SD	Standard Deviation
SEAT	Seat Effective Amplitude Transmissibility
WBV	Whole-Body Vibration

# CHAPTER 1

## INTRODUCTION

This chapter describes a brief introduction to the background of this research. Subsequently, the objectives and the corresponding hypotheses are explained, and the necessity of the research is being justified. Next, the scope and the limitations of the study are highlighted. Finally, an overview of the thesis is discussed at the end of the chapter.

### 1.1 Research Background

Exposure to a whole-body vibration (WBV) in transports during a daily life is common. The WBV occurs when a human body is supported by a vibrating surface. It is generally transmitted through the floor, the seat surfaces and the backrests, such as through driving a car or commuting using trains. Humans' exposure to the WBV is an extensive occupational risk factor, which is commonly associated with the lower back pain (LBP). It also affects the performance and the comfort of professional drivers (Bovenzi, 2010; Mayton *et al.*, 2008).

Previous studies found that higher exposures to the WBV were associated to an off-road rather than an on-road conditions (Scarlett *et al.*, 2002; Darby *et al.*, 2010; Kim *et al.*, 2018). Thus, it is likely to exceed the health guidance caution zone of 8 hours exposure in 24 hours span, which is in accordance to ISO 2631–1 (1997) standard. WBV can cause muscle lengthening and shortening which could potentially increase the muscle tension due to a stretch reflex (Ritzmann *et al.*, 2010). Furthermore, it was reported that muscle activities were higher under the conditions with vibrations in comparison to the conditions without vibrations (Li *et al.*, 2015).

The term biodynamic is widely used in human vibration engineering practice, as mentioned in the ISO 8727 (1997). Biodynamic can be defined as the mechanical properties or responses of the body, parts and systems either with reference to impressed forces or motion, or in the relation to the body's own mechanical activity (Griffin, 2012). The most common way to describe the biodynamic response is by studying the dynamic characteristics of the human body from a measurement of the apparent mass.

According to the ISO 5982 (2001), apparent mass is the force and motion at the point of input of vibration to the body ("to the body" transfer functions). Griffin (2012) defined the apparent mass as the complex ratio of force to acceleration during simple harmonic motion, or also called as "effective mass". Current laboratory procedures for evaluating seat performances can benefits from this

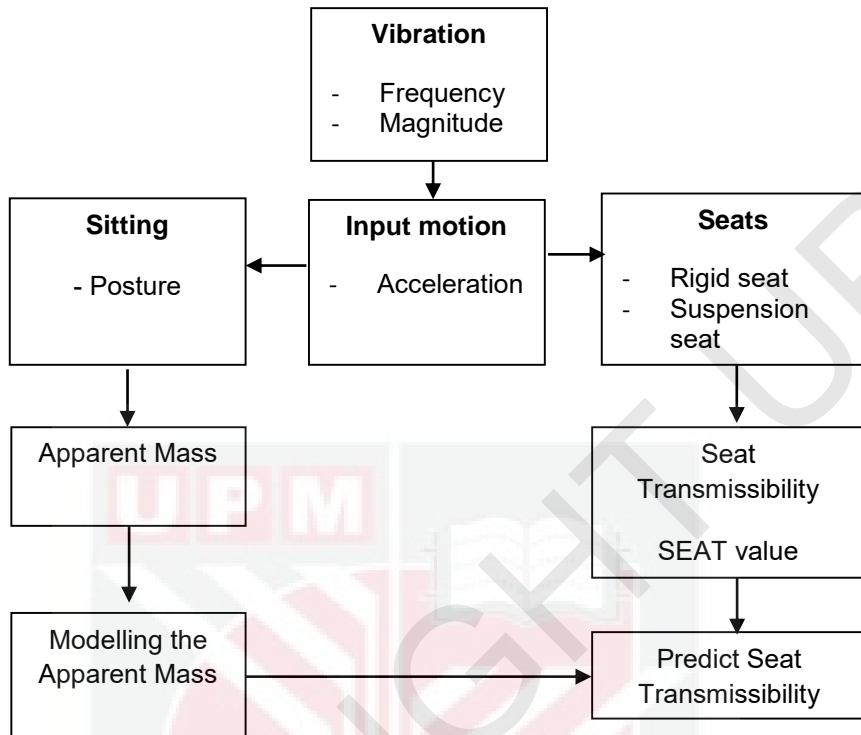

transfer function (apparent mass) under conditions similar while driving vehicles (ISO 5982, 2001). Apparent mass of the human body is commonly used as it gives insight into the dynamic behavior of the human body, representing frequencies at which the human body is most sensitive to acceleration. (Mansfield, 2005). The apparent mass has not only been used to derive models for seats assessment (Pang *et al.*, 2005; Wu and Qiu, 2019), but to identify resonance for exposure risk assessment (Rakheja *et al.*, 2008; Pranesh *et al.*, 2010) as well.

The exposure to the WBV can be reduced with a conventional or suspension seat. The conventional seat does not have its own suspension mechanism, and consist of standard foam cushion. Suspension seat has its own suspension mechanism and designed to isolate vibration at lower frequencies than normal seat (conventional seat). It is common for off-road vehicles, such as agricultural tractors to be equipped with the suspension seat. The suspension seat is aimed to reduce the effect of excessive vibration and shock to the human body. The suspension seat's efficiency depends on (i) the seat transmissibility, (ii) the input vibration at the seat base and (iii) the sensitivity of the human body to the input vibration on the seat surface (Griffin, 2012). The excitation sources such as road roughness, engine, tyres and dynamic working load are referred to input vibration.

The most common way to analyse the characteristics of a suspension seat is to measure its magnitude transmissibility. Seat transmissibility can be defined as the ratio between vibrations on the seat surface to the seat base and it is dimensionless. The characteristics of the seat and the human body are both important. The combination of the seat and the human body formed a coupled system and it is affected by each other (Lo *et al.*, 2013; Kim *et al.*, 2017). Thus, in order to predict the suspension seat performance, it is necessary to include the human response in the model as well.

The apparent mass of the human body is usually measured on a rigid seat, with less attention given for the suspension seat. However, there are evidences that type of seat could affect the apparent mass of human body (Toward and Griffin, 2011; Dewangan *et al.*, 2018). The use of suspension seat is common for agricultural tractors. Research on the contribution factors of the apparent mass of a human body seated on the suspension seat will not only improve the knowledge of the dynamic mechanisms of the human body when exposed to the WBV, but can be used to develop biodynamic models of the human body as well.

The conceptual framework of this study is shown in the Figure 1.1.

**Figure 1.1: Conceptual framework of the study**

## 1.2 Problem Statement

### 1.2.1 Effect of Sitting Postures and Vibration Magnitudes on the Vibration Transmission.

Standards have been proposed to test the seat transmissibility by using the inert mass or human subject (ISO 7096, 2000). According to the standard, the test person shall adopt a natural upright posture. However, in a normal working condition, human body adopted various postures depending on the farm activities. In addition, the variation in vibration magnitudes also been influenced by the work surface and the speed of the tractors. These variables may affect the performance of the suspension seat, and thus affect the vibration transmission through the suspension seat. Nevertheless, it's remained unclear on how these factors affecting the suspension seat performance.

### **1.2.2 Influence of the Suspension Seat on the Apparent Mass of a Seated Human Body**

Seated human bodies on the rigid seat and exposed to the WBV have been extensively investigated in various experimental conditions. (Matsumoto, 2002, Rakheja *et al.*, 2010; Dewangan *et al.*, 2018). Changes in the seating condition will influence the human responses (Griffin, 2012). A suspension system introduces a degree of freedom between the subject's ischial tuberosity when in contact with the seat pan, which allows the relative movement of the hip. However, to date, limited studies have been reported on the apparent mass of the seated human body on a suspension seat.

### **1.2.3 Modelling the Apparent Mass of a Seated Human Body on the Suspension Seat.**

Both suspension seat and a human subject have close natural frequency. Suspension seat and a human body form a combined dynamic system that affect the seat transmissibility. The human body introduces another degree-of-freedom to the system. The influence of the human body to the seat transmissibility may be caused by the seat dynamics or the response of a human body, or may be caused by the combined effect of both the seat dynamics and the response of a human body. The influence of these factors on the relative contributions of variations in the biodynamic response and variations in the seat transmissibility are not known. Thus, this research seeks to find the mechanics underlying the non-linearity of the human body to develop a mathematical model of the apparent mass. The modelling from the apparent mass will help to understand the dynamic response of seated human body seated on suspension seat.

### **1.2.4 Incorporating Human Response with Suspension Seat for the Prediction of Seat Transmissibility**

Off-road vehicles are usually driven on rough surfaces, which cause severe vibrations. These vibrations are usually low in frequency, ranging below 5 Hz (Zhou, 2014; Yan *et al.*, 2015). Vibrations at low excitation frequencies (1 - 20 Hz) are the main risk factors for the musculoskeletal disorders, which can reduce the work efficiency of drivers and passengers (Burström *et al.*, 2015; Scarlett *et al.*, 2007; Smets, 2010). Thus, such vibrations require isolation.

Previous researchers have noted that the human body cannot be simply replaced with a rigid mass (Toward, 2010; Panta *et al.*, 2014). However, limited studies on the modelling of the agriculture suspension seat have considered the human responses. Thus, the need of a suspension seat-human body model is crucial to predict the dynamic performance of the suspension seat when exposed to the WBV.

### **1.3 Objectives**

#### **1.3.1 Main Objective**

The main objective of the thesis is to predict the suspension seat transmissibility when exposed to the vertical WBV. The objective can be achieved by investigating the seat transmissibility and the apparent mass of a seated human body on the suspension seat. The specific objectives are described below.

#### **1.3.2 Specific Objectives**

- i. To investigate the effects of sitting postures and vibration magnitudes on the vibration transmission of a suspension seat.
- ii. To investigate the apparent mass of a seated human body on the rigid and suspension seat.
- iii. To develop a mathematical model of the apparent mass of a seated human body on the suspension seat.

### **1.4 Research Questions and Hypotheses**

This thesis aims to answer four main questions:

- i. Is the sitting postures and vibration magnitudes affect the vibration transmission of a suspension seat?
- ii. How the apparent mass of a seated human body is different from rigid and suspension seat?
- iii. How to develop a mathematical model of the apparent mass of a seated human body on the suspension seat?
- iv. Can the response of human body be included in the modelling to predict the seat transmissibility?

It was hypothesized that:

- i. The sitting postures and vibration magnitudes would affect the vibration transmission of a suspension seat.
- ii. The resonance frequency of the apparent mass of the seated human body would reduce when seated on the suspension seat.

- iii. The apparent mass of a seated human body can be represent by the lumped parameter models.
- iv. The response of the human body is combined with the response of the suspension seat by using lumped parameter model to predict the seat transmissibility.

## **1.5 Significance of the Study**

The present study is important to advance the understanding on the response of a human body when seated on the suspension seat. The suspension seat is an important component of the agricultural machineries for isolating the vibration transmitted to the driver and for reducing the discomfort and health risk. An in-depth understanding in the characteristics of suspension seats and biodynamic responses of a human body seated on the suspension seat can assist manufacturers in optimising the seat design.

In addition, the study proposed the method of prediction of seat transmissibility. Thus, it is useful for the industry to identify the performance of the suspension seat that meets their usage and consequently improves the safety of the workers from an excessive exposure to the WBV.

## **1.6 Scope and Limitation of the Study**

### **1.6.1 Scope of the Study**

The scope of the study is simplified as in Figure 1.2. Three main categories are explored, which includes factors affecting biodynamic responses of the seated human body, seats, and vibration input. The apparent mass measurement leads to the development of a lumped parameter model of a seated human body on a suspension seat. In addition, the suspension seat transmissibility are investigated. Both the data will be used to predict the suspension seat transmissibility.

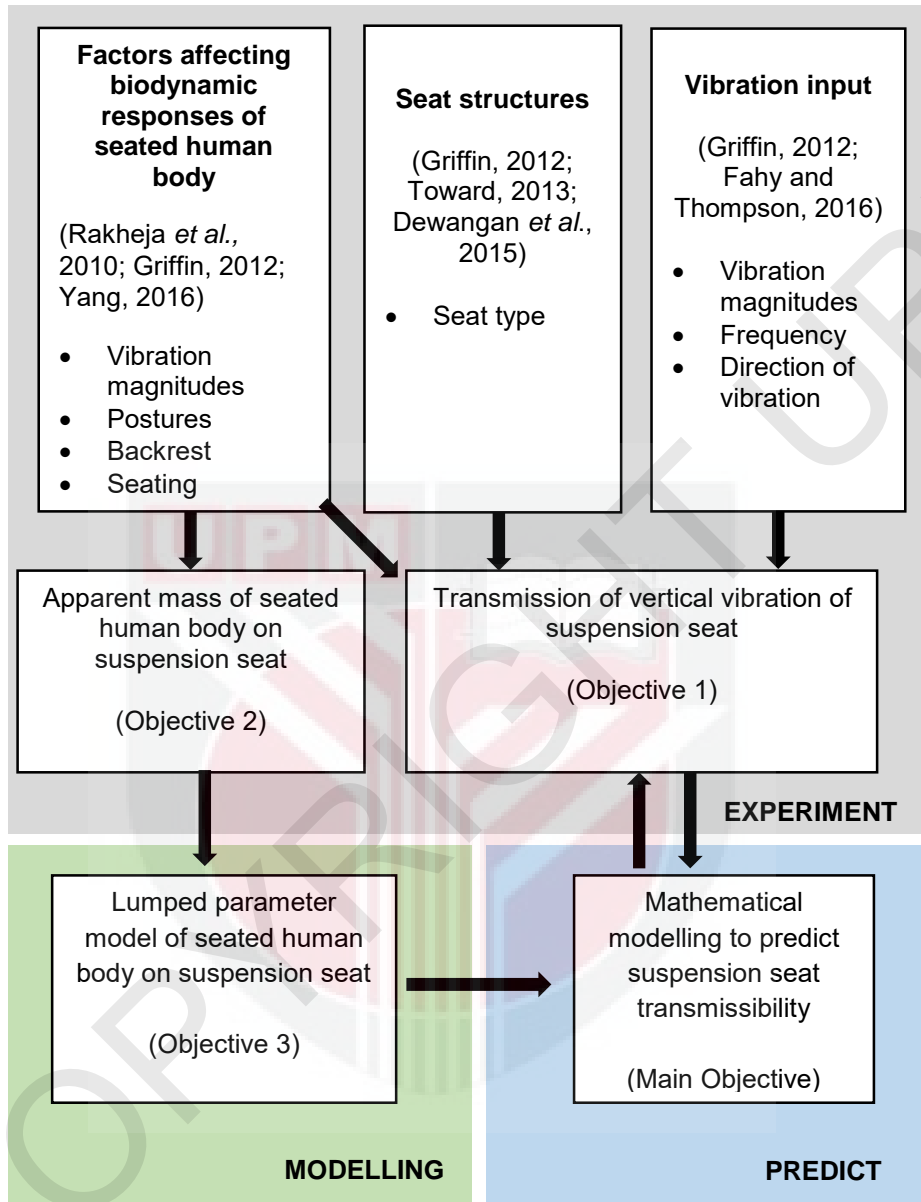

Figure 1.2: Simplified diagram representing the scope of the study

### **1.6.2 Limitation of the Study**

The suspension seat used in the study is limited to a passive suspension seat. The reason for such a suspension seat is studied is because it is commonly used in the agriculture industry in Malaysia. Hence, it would be helpful to use the suspension seat that is commonly used in the industry. Nevertheless, the contribution of the knowledge gain from this research can be applied to different types of suspension seats.

### **1.7 Thesis Layout**

Overall, the thesis comprises of five chapters.

Chapter 1 introduces the research. An overview of the research background is presented.

Chapter 2 describes the related studies of a human response to the WBV, the suspension seat transmissibility and the existing models of a seated human body. The knowledge gap is highlighted at the end of the chapter.

Chapter 3 specifies the equipment, material, methodology and data analysis used in the thesis. The flow and experimental design of the research are presented in this chapter.

Chapter 4 investigates the vibration transmission and the human responses on the suspension seat. The effect of the vibration magnitudes, postures and the backrest support are explored. Then, mathematical models are proposed to predict the suspension seat transmissibility. A general discussion of the findings are reported at the end of the chapter.

Chapter 5 concludes the main findings of the study, along with the recommendation for future research.
