*Eucalyptus pellita* is currently the predominant tree species deployed for tree plantation establishment in Sabah and Sarawak, Malaysia. Its low disease susceptibility, good growth and form, and desirable wood properties make *E. pellita* particularly suitable for plantation development in the wet tropical regions of south-east Asia. In spite the many positive traits, practical field observations indicate that the species is susceptible to end-grain splitting. This study evaluates the occurrence and severity of end-grain splitting in plantation grown *E. pellita* in Sabah and Sarawak as affected by genetics, environment and growth attributes. The study further evaluates the effectiveness of three split remedial measures. Four existing progeny tree breeding trials were used to carry out the split assessment. Logs from the second thinning were cut into 2.2 m long sections. The end splits were assessed three days later at large and small log end. Three split remedial measures were tested and compared against a control in a separate progeny trial in Sabah. Plastic s-hooks, wax and bitumen emulsions were applied to the cut surface and assessed two weeks later. In this study, *E. pellita* showed a high tendency towards end-grain splitting. About 96% of all logs showed some signs of splitting on its cross-sectional surface with an average of 2.7 splits per cut surface. In average 9.06% of the log volume is compromised due to end-grain splitting. Three-Quarter Radial Splits were the most frequently observed split types with 64% occurrence rate, followed by Pith to Bark Splits with 27%. End-grain splitting in *E. pellita* is heritable ( $h^2 = 0.24$  at  $p \leq 0.05$ ). This implies that about 24% of the observed splitting is due to genetics. The trait end-grain splitting therefore can be altered via genetic selections in breeding programs. End-grain splitting also is found to be significantly related to growth factors such as tree height, diameter at breast height (DBH) and tree volume. Increased growth is associated with an increase in split incidence and severity. The unfavorable relationship between growth and log end-grain splitting requires careful selections of high volume and low split genetic material for breeding

purpose. Environmental factors, especially soil texture with varying clay- sand- silt content, were found to have a significant effect on log end-grain splitting as well as on growth comparing different sites. Application of plastic s-hooks reduced significantly (49.62%) split occurrence and severity, while the wax and bitumen end sealers had no effect on reduction of growth strain related splits. The findings suggest that end-grain splitting is caused by heritable, complex genetic–environment–growth interactions.

*Eucalyptus pellita* kini merupakan spesies pokok yang utama untuk industri penanaman pokok di Sabah dan Sarawak, Malaysia. Ketahanan terhadap penyakit, pertumbuhan, bentuk pokok yang baik, dan ciri-ciri kayu yang diterima umum menjadikan *E. pellita* sangat sesuai sebagai pembangunan ladang di kawasan tropika yang lembab terutamanya di Asia Tenggara. Walaupun terdapat banyak ciri-ciri menarik yang dilihat pada spesies pokok ini, namun beberapa pemerhatian di lapangan secara praktikal menunjukkan bahawa spesies ini mudah merekah. Kajian ini menilai masalah kayu merekah dan tahap keparahan masalah tersebut di ladang penanaman pokok *E. pellita* yang ditanam di Sabah dan Sarawak yang di mana dipengaruhi oleh sifat genetik pokok, persekitaran dan pertumbuhan. Kajian ini juga bertujuan untuk menilai keberkesanan tiga langkah-langkah pemuliharaan masalah kayu merekah. Terdapat empat kawasan kajian terhadap baka pokok yang sedia ada bagi menjalankan kajian ini. Pokok yang ditebang semasa kerja penjarangan pokok yang ke dua dipotong kepada 2.2 m bahagian. Kayu merekah dinilai tiga hari kemudian pada setiap kedua bahagian hujung besar dan hujung kecil setiap kayu yang dipotong. Tiga langkah-langkah pemuliharaan kayu merekah telah digunakan dan ia dibandingkan dengan jenis pemuliharaan kawalan di dalam Kawasan kajian baka pokok di Sabah. Cangkuk plastic jenis S, wax dan bitumen telah digunakan pada permukaan kayu dan dinilai selepas dua minggu kemudian. Dalam kajian ini, *E. pellita* menunjukkan mempunyai risiko tinggi terhadap masalah kayu merekah. Kira-kira 96% daripada semua sampel kayu menunjukkan beberapa rekahan pada permukaan keratan rentas kayu dengan rata-rata 2.7 bahagian permukaan yang dipotong. Sederhana 9.06% daripada isipadu kayu adalah kurang bernilai oleh kerana rekahan kayu tersebut. Rekahan jejari tiga Suku adalah jenis kerosakan yang paling banyak diperhatikan dengan kadar 64%, diikuti oleh rekahan dari dalam hingga ke kulit dengan kadar 27%. Keperahan kayu merekah menunjukkan boleh mewarisi ( $h^2 = 0.24$  pada  $p \leq$

0.05). Bermaksud 24% dari rekahan kayu adalah kerana genetik pokok tersebut. Oleh itu rekahan kayu tersebut boleh berubah dari pemilihan genetik dalam program pembiakan. Kejadian kayu merekah juga didapati ada kaitannya secara signifikan dengan faktor pertumbuhan seperti ketinggian pokok dan ukur lilit pokok (DBH). Faktor persekitaran, terutamanya tekstur tanah seperti campuran tanah liat-pasir-lumpur yang berbeza-beza juga mempunyai kesan yang signifikan terhadap kejadian kayu merekah dan juga factor pertumbuhan di Kawasan kajian yang berbeza. Bagi spesies *E. pellita* penggunaan cangkuk plastik jenis S dapat mengurangkan (49.62%) daripada masalah dan juga tahap keparahan kayu merekah, sementara itu wax dan bitumen tidak mempengaruhi kadar pengurangan kayu merekah yang dimana ianya disebabkan oleh tekanan dari pertumbuhan. Hasil kajian ini menunjukkan bahawa kejadian kayu merekah disebabkan oleh interaksi antara genetik pokok dengan persekitaran dan juga pertumbuhan yang sangat kompleks.

## ACKNOWLEDGEMENTS

My thank go to all the people, my families and friends, who have supported me to complete the research work direct or indirectly.

This thesis was submitted to the Senate of Universiti Putra Malaysia and has been accepted as fulfilment of the requirement for the degree of Master of Science. The members of the Supervisory Committee were as follows:

**Paridah Md Tahir, PhD**

Professor  
Institute of Tropical Forestry and Forest Product  
Universiti Putra Malaysia  
(Chairman)

**Lee Seng Hua, PhD**

Research Fellow  
Institute of Tropical Forestry and Forest Product

## CHAPTER 1

### INTRODUCTION

#### 1.1 Background of the study

*Eucalyptus pellita* F. Muell., also known as red mahogany, occurs naturally in the tropical regions of north-eastern Queensland, Australia and the island of New Guinea. It can reach heights of up to 40 m and about 1 m diameter at breast height with a usually straight stem form. It grows in gentle to moderate sloping terrain mixed with other eucalypt species in tall open forest and at the fringes to tropical rainforest. It prefers sand to loam soil types with good drainage at altitudes from sea level to 800 m asl with moderate to high rainfall of 900 to 4000 mm annually (Brooker and Kleinig, 2012). It is one of the few eucalyptus species that is adapted to the wet tropical climate and is thus less susceptible to fungal leaf pathogens (Harwood et al., 1997). This adaptation together with other positive traits make it suitable for plantation establishment in wet tropical regions outside of its natural range.

The recent devastation caused by *Ceratocystis* vascular wilt disease (Tarigan et al., 2010 and Brawner et al., 2015), has resulted in almost all *Acacia mangium* Willd. plantations in the Malaysian states of Sabah and Sarawak being replaced by *E. pellita*. Since 2012, large scale *E. pellita* plantations and tree breeding orchards have been established in Sabah, as well as in Sarawak (Paridah et al., 2017). Japarudin et al. (2020) have shown *E. pellita* to have highly productive growth in Sabah (mean annual increment, MAI, 27.6 m<sup>3</sup> ha<sup>-1</sup> y<sup>-1</sup>) compared to other potential species in a taxa trial. Studies revealed that among the three species, namely *E. grandis* W. Hill, *E. urophylla* S.T. Blake and *E. pellita*, *E. pellita* has superior characteristics in both growth rate and wood properties (Prasetyo et al., 2017). Hii et al. (2017) and Japarudin et al. (2021) studied the properties of *E. pellita* from Sarawak and Sabah and found that it possesses good properties for solid wood and veneer which are consistent with those reported by earlier studies (Atyeo and Bailleres, 2008). Unfortunately, the studies also confirmed the tendency of *E. pellita* towards end-grain split formation with significant reduction in higher grade solid wood recovery (Japarudin, 2021). The solid wood recovery of *E. pellita* can be reduced as much as 50% as the viable log length decreases with larger aggregates of end-grain splits (Japarudin, 2021).

### 1.1.1 Incidence of End-Grain Split in Eucalyptus Logs

Many studies have associated growth stress with increase in severity of end-grain split in logs. Beltrame et al., (2015) investigated the relationships between level of longitudinal residual strain (DRL) and the longitudinal growth stresses (TCL) and their effects on the amount of logs end-grain splitting (IRT) of Eucalyptus spp. They discovered that there were significant and positive correlations between DRL/TCL variables with IRT. Thus, it is possible to predict the trend of IRT by performing an evaluation of DRL in the field. Owing to that, this variable becomes a reliable tool for the selection of clones less prone to splitting (Beltrame et al., 2015). High magnitude of longitudinal growth stresses has a significant implication on recovery and processing of high quality timber. Although the longitudinal growth stresses are inherent to all trees, their magnitude varies from species to species, and also within species. These stresses cause ring shake and brittle heart in standing trees, end-grain splitting in logs within a short time span of felling a tree, severe splitting in timber immediately after sawing, and twisting and cracking in timber during drying (Malan, 2009 and Yang, 2005). Hence growth stresses have become a major wood quality criterion in the selection of superior genetic material and also assessing the economic values of logs. Addressing log end-grain splitting and distortion of timber due to growth stress is necessary if Eucalypts are to succeed in solid wood or in veneer markets (Sharma et al., 2017).

### 1.1.2 Remedial Measures to Prevent or Mitigate End-Grain Splitting

Knowledge on suitable remedial measures to reduce *E. pellita* wood degradation due to end-grain splitting is very limited. It seems that no research has been carried out yet in Malaysia and published research data pertaining such topic does not exist. Remediation measures are designed to prevent, reduce or mitigate splitting of plantation logs or finished solid wood end products. Generally, two methods can be identified: 1.) Products that physically hold or bind the wood together (Max Amrhein GmbH, S-hooks, company website) and 2.) Products which are applied to reduce moisture loss and therefore reduce split formation (Hernandez and Wengert, 1997; Rice, 1995). The first group of products usually comprises of metal s-hooks, rings or gang nails which are driven into the wood by hammer. It is a common practice in Malaysia, as well as in other countries (Guyana Forestry Commission, 2012), to apply metal s-hooks to the large and small end of the log. Usually this is carried out during log making or stockpiling of logs along the road side, awaiting transportation. Metal s-hooks are readily available in Malaysia and it is a relatively cheap method compared to end coating. Logging contractors and workers are familiar with the use of s-hooks and it is seen as a method that works. This is despite the fact that there is no clear evidence or prove for its effectiveness. It appears that there are no studies and publications regarding use and effectiveness of s-hooks. A limitation of metal s-hooks is that they need to be removed before log processing. Usually, the log portion containing the s-hook is cut off and becomes a waste product,

which increases the operational cost. Plastic s-hooks are relatively soft and can be cut by saws or other machinery, due to this they don't need to be removed. On the other hand, side plastic s-hooks are not as strong and solid as metal s-hooks and do not withstand larger wood stresses. Plastic s-hooks are smaller compared to metal s-hooks and appear to be more suitable for smaller sized plantation logs.

Although s-hooks seem to reduce the severity and occurrence of splitting in round logs, they do not alter the residual growth stresses and the wood is still very likely to split during downstream processing (Yang and Waugh, 2001). The second product group comprises of different emulsion pastes such as paraffin, silicon, petroleum jelly, wax, bitumen or oils which are sprayed or applied by a brush to the wood surface (Hernandez and Wengert, 1997; Rice, 1995). There are many different products available on the market which all promise to be effective. Applying end coatings to round logs after felling and log making is not a common practice in Malaysia and rarely can be observed in logging operations. Use of end sealers appears to be common during downstream processing and is described as a standard practice in sawmills to prevent splitting (Linares-Hernandez and Wengert, 1997). Coatings reduce and delay the moisture loss from log ends or the wood surface and allow an even drying and shrinkage of the wood core and its periphery, thus resulting in reduced drying stresses and low splitting (Yang and Normand, 2012). Most commercial log and lumber sealers are described as being effective in split reduction with little statistically significant variation (Rice, 1995). Suitable operational timing of end sealer application is crucial and should be carried out within seven days after felling (Yang and Normand, 2012).

In this study plastic s-hooks, a wax emulsion end sealer and a bitumen end sealer are used and compared against a control of no remedial application.

## 1.2 Research Questions

This study intends to provide answers to the following research questions:

1. Is end-grain splitting in *E. pellita* related to genetics?
2. Is end-grain splitting in *E. pellita* related to environmental factors?
3. Is end-grain splitting in *E. pellita* related to growth factors?
4. Are there suitable remediation measures to prevent or mitigate end-grain splitting in *E. pellita* plantation logs?

### 1.3 Statement of Problems and Justifications

The occurrence of end-grain splitting in planted *E. pellita* logs in Malaysia is poorly understood. Reports published on this topic are very few which may be due to the lack of research being carried out concerning such topic. The research questions raised in this thesis are crucial in determining the true value of *E. pellita* as the future source of wood material. However, very little information pertaining to these questions have been reported so far. For instance, the published research mainly discussed about recovery loss due to splits and do not cover a wider range of aspects involved in log end-grain splitting, particularly the genetic influence on the extent of the end-grain splitting. In order to ensure long term productivity, high grade log recovery and optimum utilization of *E. pellita* wood products, comprehensive information and knowledge on the end-grain splitting incidents are vital so that higher economic returns of *E. pellita* plantations in Malaysia can be secured.

### 1.4 Objectives

It is the objective of this study to provide detailed answers to the raised research questions. The specific objectives of the study are:

- i. To evaluate the occurrence and severity of end-grain splitting in *E. pellita* as affected by heredity and family.
- ii. To evaluate the occurrence and severity of end-grain splitting in *E. pellita* as affected by growth factors.
- iii. To evaluate the occurrence and severity of end-grain splitting in *E. pellita* as affected by environment/ site factors.
- iv. To evaluate the effectiveness of three split remedial methods in reduction of end-grain splitting of *E. pellita* logs.

Knowledge gained from this study shall contribute to improve the management of *E. pellita* tree plantations and the maximization of value creation. It is intended to identify if statistically significant differences in log end-grain splitting do exist on an individual family level. In relation to this, it is targeted to determine if splitting as a wood property trait in *E. pellita* is heritable. This is important in order to determine in how far the occurrence and severity of log end-grain splitting can be altered via genetic selections as a breeding strategy.

It is further envisaged to clarify if different soil/ environment conditions contribute to end-grain splitting in *E. pellita* plantation logs. In combination to different site conditions, it is planned to identify if variation in growth rate has an effect on log end-grain splitting. Knowledge concerning this can be incorporated in annual harvesting planning and application of suitable split remediation measures. This study intends to provide information on suitable remedial measures which can be applied after tree felling and log making in order to reduce split occurrence and severity.

### **1.5 Organisation of Thesis**

This thesis contains the following chapters:

1. Introduction
2. Literature Review
3. Materials and Methods
4. Results
5. Discussion
6. Summary, Conclusions and Recommendations for Future Research
